# STATUS OF WILDLIFE POPULATIONS, FALL 2006 

(Including 1995-2005 Hunting and Trapping Harvest Statistics)

edited by<br>Margaret H. Dexter<br>Minnesota Department of Natural Resources<br>Division of Fish and Wildlife<br>Wildlife Research and Policy Unit<br>Saint Paul, Minnesota<br>1 (888) 646-6367<br>http://www.dnr.state.mn.us

© November, 2006 State of Minnesota, Department of Natural Resources
Equal opportunity to participate in and benefit from programs of the Minnesota Department of Natural Resources is available to all individuals regardless of race, color, creed, religion, national origin, sex, martial status, status with regard to public assistance, age, sexual orientation, membership or activity in a local commission, or disability. Discrimination inquiries should be sent to MN-DNR, 500 Lafayette Road, St. Paul, MN 55155-4031; or the Equal Opportunity Office, Department of the Interior, Washington, DC 20240.

Printed on recycled paper containing a minimum of 30\% post-consumer waste and soy-based ink
This report should be cited as follows:
Dexter, M.H., editor. 2006. Status of wildlife populations, fall 2006. Unpub. Rep., Division of Fish and Wildlife, Minn. Dept. Nat. Res., St. Paul, Minnesota. 280 pp.

Note: Data in this report may change as a result of future verification and more comprehensive analysis.

## (Including 1995-2005 Hunting and Trapping Harvest Statistics)

This is the $30^{\text {th }}$ year that the DNR has compiled this booklet; it is primarily an administrative document intended for DNR personnel. (Since 1984 we have also generated a companion volume, Summaries of Wildlife Research Findings, containing annual summaries of activities and findings from ongoing research projects in the Wildlife Policy and Research Unit). This publication will be posted on the DNR website and available on CD. In the on-line format links are available to the U.S. Fish and Wildlife Service Division of Migratory Bird Management to access their reports for Waterfowl Population Status; Migratory Bird Harvest Information Preliminary Estimates; American Woodcock Population Status; and Mourning Dove Population Status. There are three additional reports this year regarding harvest statistics from special hunts for Canada geese and Light geese (snow, blue, and Ross').

Most of the fieldwork associated with collection of census and survey data for farmland, wetland, and forest wildlife is performed by wildlife biologists and managers (conservation officers also participate in August roadside counts). The Farmland, Wetland, and Forest Wildlife Population and Research groups coordinate these activities, analyze and interpret data, and prepare recommendations for harvest regulations and season setting.

Most of the hunting and trapping harvest estimates are calculated and summarized by St. Paul central office personnel.

Compiling and publishing this report was funded in part under the Federal Aid in Wildlife Restoration Act, Minnesota project W-69-S.

## TABLE OF CONTENTS

## Wildlife Populations And Surveys

Farmland Wildlife ..... 1-34
2006 Minnesota August Roadside Survey ..... 3-18
Population Trends of White-Tailed Deer in Minnesota's Farmland/Transition Zone, 2006 ..... 19-28
Fetus Survey Data Results of White-Tailed Deer in the Farmland/Transition Zone of Minnesota, 2006 ..... 29-34
Wildlife Damage Complaints ..... 35-44
Predator Scent Post Survey And Winter Track Indices. ..... 45-60
Furbearer Winter Track Survey Summary, 2005 ..... 47-52
Predator/Furbearer Scent Station Survey Summary, 2005 ..... 53-60
Forest Wildlife ..... 61-102
Grouse Surveys In Minnesota During Spring 2006 ..... 63-76
Registered Furbearer Population Modeling, 2006 Report ..... 77-89
Population Trends Of White-Tailed Deer In The Forest Zone, 2006 ..... 90-98
Aerial Moose Survey, 2006 ..... 99-102
Migratory Birds ..... 103-136
2006 Minnesota Waterfowl Breeding Population Survey ..... 105-119
Excerpt from Waterfowl Population Status, 2006 ..... 120-124
Minnesota Spring Canada Goose Survey, 2006 ..... 125-127
Excerpt from Mourning Dove Population Status, 2006 ..... 128-131
Excerpt from American Woodcock Population Status, 2006 ..... 132-136
Hunting and Trapping Harvest Statistics
Hunting ..... 137-248
2005 Small Game Hunter Mail Survey ..... 139-148
Excerpt from Migratory Bird Harvest Information, 2005: preliminary estimates ..... 149-152
2004 September Special Canada Goose Hunt ..... 153-156
2005 September Special Canada Goose Hunt ..... 157-160
2006 Light Goose Conservation Order Harvest ..... 161-163
2005 Fall Wild Turkey Harvest Report ..... 164-167
2006 Spring Turkey Harvest Report ..... 168-189
Minnesota Prairie-Chicken Hunting Season and Hunter Survey ..... 190-195
2005 Deer Harvest Report. ..... 196-235
2005 Bear Harvest Report ..... 236-245
2005 Moose Harvest Report ..... 246-248
Trapping ..... 249-258
2005 Trapper Harvest Survey ..... 251-256
Minnesota Fur Buyers Survey for the 2005-06 Hunting and Trapping Season ..... 257-258
Registered furbearers ..... 259-280
Registered Furbearer Harvest Statistics, 2005-06 Report ..... 261-280

## FARMLAND WILDLIFE POPULATIONS

Farmland Wildlife Populations and Research Group 35365 800 ${ }^{\text {th }}$ Avenue
Madelia, MN 56062-9744
(507) 642-8478

#### Abstract

Population indices for ring-necked pheasants in 2006 were similar to last year. Gray partridge, cottontail rabbit, white-tailed jackrabbit, and deer indices were also similar to 2005, whereas mourning dove increased by $50 \%$. The winter of 2005-06 was average to mild throughout Minnesota's agricultural zone, and spring weather was warm and dry. Overwinter survival of farmland wildlife in 2006 was probably above average, and reproductive success was moderate.

Although the pheasant index ( $113.8 \mathrm{birds} / 100 \mathrm{mi}$ ) was similar to last year, it was $75 \%$ above the 10-year average, but remained $58 \%$ below the benchmark years of 1955-64 (soil-bank years with marginal cropland in long-term set-aside, a diversified agricultural landscape, more small grains and tame hay, and less pesticide use). Adult pheasants indices increased from 2005, which reflects improved overwinter survival from last year, whereas reproductive success was similar to last year. Overall, the size of the fall population will be close to 2005 levels. The best opportunity for harvesting pheasants appears to be in the Southwest region, although good opportunities will likely also be available in the West Central and Central regions.

The gray partridge index was similar to last year, $43 \%$ below the 10 -year mean, and $58 \%$ below the long-term average. No significant changes were observed at the regional level. The number of adults observed was similar to last year, but broods/adult decreased in 2006. Gray partridge counts were highest in the Southwest region.

The cottontail rabbit index was similar to last year, increased from the 10-year average, and was similar to the long-term average. Counts of cottontail rabbits were highest in the Southwest, Central, Southeast, and South Central regions. The jackrabbit index also held steady in 2006. The statewide index was also similar to the 10 -year average, but was $86 \%$ below the long-term average. The range-wide jackrabbit population peaked in the late 1950's and declined to its lowest level in 1993, from which populations have not recovered. Counts of white-tailed jackrabbits were highest in the Southwest region.

The number of mourning doves observed in 2006 increased $50 \%$ from last year, $37 \%$ above the 10 -year average, and was similar to the long-term average. Counts increased significantly in 5 of 7 regions.

## INTRODUCTION

This report is a summary of the 2006 Minnesota August roadside survey. The annual survey is conducted during the first 2 weeks in August by Minnesota Department of Natural Resource (MNDNR) enforcement and wildlife personnel throughout the farmland region of Minnesota (Figure 1). The August roadside survey consists of 17025 -mile routes (1-4 routes/county); 151 routes are located in the ringnecked pheasant range.

Observers drove each route in the early morning at 15-20 miles/hour and recorded the number of pheasants, gray (Hungarian) partridge, cottontail rabbits, white-tailed jackrabbits, and other wildlife they saw. Counts conducted on cool, clear, calm mornings with heavy dew yield the most consistent results because wildlife, especially pheasants, gray partridge, and rabbits, move to warm, dry areas (e.g., gravel roads) during early-morning hours. The data provide an index of relative abundance and are used to monitor annual changes and long-term trends in regional and range-wide populations. Results were reported by agricultural region and range-wide; however, population indices for species with low detection rates are imprecise and should be interpreted cautiously.

## ACKNOWLEDGMENTS

I thank all cooperators for their efforts in completing routes in 2006, without their help the survey would not be possible. Tonya Klinkner provided assistance with data entry. Kurt Haroldson reviewed and provided comments on drafts of this report. Tabor Hoek of the Minnesota Board of Water \& Soil Resources (BWSR) provided enrollment data on cropland-retirement programs in Minnesota.

## 2005-2006 Weather Summary

The severity of the winter of 2005-06 was moderate to mild throughout most of the pheasant range in Minnesota (the fifth consecutive mild winter). The winter started harshly with continuous snow cover through most of December (MCWG, http://climate.umn.edu/doc/snowmap.htm). However, a warm January (mean temperature 17 degrees above the long-term average; MCWG, http://climate.umn.edu/cawap/monsum/ monsum.asp) eliminated most snow from the southern pheasant range, whereas deep snow persisted in the northern half of Minnesota including the northern pheasant range. Northwestern Minnesota retained deep snow through the end of March. Temperature was above average statewide in April, setting the stage for conditions conducive to good wildlife production. Spring weather in May and June was generally warmer and drier than normal. One untimely bought of cold, wet weather occurred June 9-11, immediately following the normal peak of Minnesota's pheasant hatch. Overwinter survival of farmland wildlife was probably above average; reproductive success was likely average due to generally warm, dry conditions in May and June and continuing through the summer.

## Habitat Conditions

Habitat conditions in the pheasant range continue to maintain their highest levels since the mid1990s. Over 1 million acres of habitat are currently enrolled in farm programs (e.g., CRP, CREP, RIM, WRP), and another over 650,000 acres of habitat are protected as Wildlife Management Areas (WMA) and Waterfowl Protection Areas. Within the pheasant range, protected grasslands account for about 6.1\% of the landscape (range: 2.9-10.5\%; Table 1).

Farm programs make up the largest portion of protected grasslands in the state. Sign-up for the Minnesota CREP II began June 2005 targeting enrollment of up to 120,000 new acres of environmentally sensitive cropland in the Red River Watershed in northwestern Minnesota, the Lower Mississippi Watershed in southeastern Minnesota and the Missouri/Des Moines River Watershed in southwestern Minnesota. Although progress continues on the CRP and CREP II, the expiration of a large proportion of existing CRP contracts beginning in 2007 is still a major concern for future wildlife populations. Reenrollment and extension opportunities for CRP contracts expiring from 2007 to 2010, announced this year, may capture many of the contracts that will expire starting in 2007.

The MNDNR continues to expand the habitat base through accelerated WMA acquisition. In addition the Working Lands Initiative will attempt to protect and expand large wetland-grassland complexes in 12 counties in western Minnesota.

## Survey Conditions

Cooperators completed 170 routes in 2006; one route in Washington County was conducted, but the data were not received in time to include in this report. Weather conditions during the survey ranged from excellent (calm, heavy dew, clear sky) to medium (light dew and overcast skies). Medium-to-heavy dew conditions were present at the start of $96 \%$ of the survey routes, which was better than 2005 ( $91 \%$ ) and the 7 -year average ( $91 \%$ ). Clear skies ( $<30 \%$ cloud cover) were present at the start of $89 \%$ of routes, with wind speeds $<4 \mathrm{mph}$ recorded for $76 \%$ of routes. The survey period was extended from July $27^{\text {th }}$ to August $17^{\text {th }}$ to allow all routes to be completed.

## Ring-Necked Pheasant

The average number of pheasants observed per 100 miles was similar to 2005 and $75 \%$ above the 10 -year average (Table 2; Figure 2A). The pheasant index was similar to the long-term average (Table
2), but remained below the benchmark years of 1955-64 by 58\%. Total pheasants observed per 100 miles ranged from 29.8 in the Southeast to 242.2 in the Southwest (Table 3, Figure 5). Changes from last year were not significant in any region (Table 3).

The range-wide hen index (hens/100 mi) increased 21\% (95\% CI: 7-35\%) from last year (Table 2), and varied from 5.2 hens/ 100 miles in the Southeast to 41.2 hens $/ 100$ miles in the Southwest. The cock index also increased this year, up 49\% (95\% CI: 26-72\%) from 2005 (Table 2). The 2006 hen:cock ratio was 1.6 compared to 2.0 in 2005 and 1.3 in 2004. Given the above-average fall population in 2005 and likely above-average overwinter survival, the spring breeding population should have been higher than average. Data from spring pheasant surveys, conducted as part of a CRP/pheasant study, indicated unusually high breeding pheasant populations, with a 95\% increase in hen indices from 2005 (Kurt Haroldson, MNDNR, unpublished data). These surveys were conducted on 36 study areas located in Lincoln, Lyon, Cottonwood, and Jackson Counties in the Southwest; Pope County in the West Central; and LeSueur, and Rice Counties in the South Central region during April 20 - May 27.

The number of pheasant broods observed per 100 miles increased $13 \%$ from last year, $77 \%$ from the 10 -year average, and $35 \%$ from the long-term average (Table 2). The brood index continues to remain below the benchmark years (1955-64). Regional brood indices ranged from 5.2 broods/ 100 miles in the Southeast to 37.8 broods $/ 100$ miles in the Southwest. Average brood size in 2006 ( $4.8 \pm 0.1$ [SE] chicks/brood) was similar to last year ( $5.0 \pm 0.1$ [SE] chicks/brood), the 10-year mean ( 5.0 chicks/brood), but below the long-term average ( 5.6 chicks/brood; Table 2). The median hatch date for pheasants was June $8(n=663)$, the same as last year and 1 day later than the 10 -year average (Table 2). The distribution of estimated hatch dates for observed broods was unimodal and approximately normally distributed, which suggests that many early nesting attempts were successful (vs. wide-spread nest failure, which often leads to an extensive renesting effort and a bimodal peak in hatch dates). Average age of broods observed was 8.2 weeks (range: $1-16 \mathrm{wks}$ ).

A high range-wide pheasant index was expected given the mild winter and warm, dry weather during the reproductive season. The combination of relatively high hen numbers and average reproductive success led to a large pheasant index for 2006. In addition the increase in the cock index indicates higher than average carryover from the 2005 reproductive season. Overall, the size of the fall population will be similar to 2005 levels. The best opportunity for harvesting pheasants appears to be in the Southwest region, although good opportunities will likely also be available in the West Central and Central regions.

## Gray Partridge

Rangewide, the gray partridge index ( 6.3 partridge/100 miles) was similar to last year. However, the 2006 index was $43 \%$ below the 10 -year average and $58 \%$ below the long-term average (Table 2, Figure 2B). Within regions, the partridge index ranged from 0.0/100 miles in the East Central and Northwest to 28.6/100 miles in the Southwest (Table 3, Figure 6). There were no significant regional changes from last year (Table 3).

The number of adults observed per 100 miles was similar to last year, but $30 \%$ below the 10 -year mean and $45 \%$ below the long-term average (Table 2). The proportion of adult partridge observed with broods (28\%) decreased from 2005 (32\%), the 10-year average (34\%), and long-term average (33\%). Average brood size in 2006 ( 7.5 chicks/brood) was larger than in 2005 ( 7.0 chicks/brood), but smaller than the 10 -year average ( 7.9 chicks/brood) and the long-term average ( 8.9 chicks/brood). Total broods observed per 100 miles were similar to 2005, but $45 \%$ below the 10 -year average, and $55 \%$ below the long-term average (Table 2). The median hatch date was June $26(n=24)$, which was 16 days later compared to 2005 and 7 days later than the 10 -year average.

Conversion of diversified agricultural practices to more intense land-use with fewer haylands, pastures, small grain fields, and hedgerows have reduced the amount of suitable habitat for the gray partridge in Minnesota. The late median hatch date this year might indicate more renesting, possibly due to a short period of stormy weather during the nesting season. Gray partridge in their native range
(southeastern Europe and northern Asia) are associated with arid climates and only produce well in the Midwest during dry or drought years. Consequently, gray partridge are more strongly affected by weather conditions during nesting and brood rearing than are pheasants. Clutches resulting from renesting can be smaller than initial nest attempts. The Southwest region offers the best opportunity for harvesting gray partridge in 2006.

## Cottontail Rabbit And White-Tailed Jackrabbit

The eastern cottontail rabbit index ( 7.2 rabbits $/ 100 \mathrm{mi}$ ) was similar to last year, increased $19 \%$ from the 10-year average, and was similar to the long-term average (Table 2, Figure 3A). There continues to be high variability in counts and percent change by region (Table 3). The cottontail rabbit index ranged from 1.7 rabbits/ 100 miles in the Northwest to 10.9 rabbits $/ 100$ miles in the Southwest (Figure 7). The best opportunities for harvesting cottontail rabbits are in the Southwest, Central, Southeast, and South Central regions.

The index of white-tailed jackrabbits held steady in 2006. The statewide index ( 0.3 rabbits/ 100 mi ) was also similar to the 10-year average (0.5), but remained 86\% (95\% CI: 72-100\%) below the longterm average (2.0; Table 2, Figure 3B). The range-wide jackrabbit population peaked in the late 1950’s and declined to its lowest level ( 0.2 rabbits $/ 100 \mathrm{mi}$ ) in 1993, from which populations have not recovered (Figure 3B). The long-term decline in jackrabbits probably reflects the loss of their preferred habitats (i.e., small grains, pasture, and hayfields). The greatest potential for white-tailed jackrabbit hunting is likely in the Southwest region (Table 3, Figure 8). However, indices of relative abundance and annual percent change should be interpreted cautiously because estimates are based on low numbers of sightings.

## White-Tailed Deer

The index of white-tailed deer ( 15.0 deer $/ 100 \mathrm{mi}$ ) was comparable to last year and the 10-year average, and was 50\% above the long-term average (1974-05; Table 2, Figure 4A). There were no significant regional changes from 2005. The farmland deer population index shows an increasing longterm trend since 1979 (Figure 4A). Modeling projections based on independent data also indicate an increasing trend for deer populations in the farmland zone.

## Mourning Dove

The number of mourning doves observed per 100 miles in 2006 increased 50\% from last year, $37 \%$ from the 10-year average, and was similar to the long-term average (Table 2, Figure 4B). The mourning dove index ranged from 136.5 doves/100 miles in the Northwest region to 533.4 doves/100 miles in the Southwest. Significant increases in dove counts were detected in all regions but the South Central and Southeast regions (Table 3). The number of mourning doves heard along U.S. Fish and Wildlife Service call-count survey (CCS) routes $(n=8)$ in Minnesota were similar to last year. Trend analyses indicated the number of mourning doves heard along the CCS routes declined $5.2 \%$ per year ( $90 \% \mathrm{CI}$ : -10.2 to $-0.3 \%$ ) during 1997-2006 and $1.8 \%$ per year ( $90 \% \mathrm{CI}$ : -3.3 to -0.3\%) during 1966-2006 (Dolton and Rau 2006). In fall 2004, Minnesota held its first modern dove hunting season.

## Other Species

Notable incidental sightings: 1 badger (Swift County), 1 bald eagle (Polk County), 2 Cooper’s hawks (LeSueur County), 4 coyotes (Goodhue, Kandiyohi, Pine, and Roseau Counties), 6 elk (Kittson County), 1 fallow deer (Cottonwood County), 1 gray fox (Chisago County), 1 great gray owl (Marshall County), 4 green heron (Dodge and Polk Counties), 1 prairie chicken (Clay County), 3 red fox (Chisago and Wilkin County), 9 ruffed grouse (Lake of the Woods, Marshall, and Red Lake Counties), 215 sandhill crane ( 14 counties), 5 sharp-tailed grouse (Pennington County), 6 striped skunk (Dodge, Goodhue, Polk, and Wilkin Counties), 6 trumpeter swan (Brown, Douglas, and Otter Tail Counties), 248 wild turkeys and 93 turkey poults (24 counties).

Figure 1. Ring-necked pheasants seen per 100 miles of August Roadside Survey and percent change from 2005, 10-yr mean (1996-2005), benchmark (1955-1964), and long-term average (1955-2005). Benchmark reflects soil-bank years with marginal cropland in long-term set-aside, a diversified agricultural landscape, more small grains and tame hay, and less pesticide use. Note: estimates are based on all routes completed and, thus, may differ from values in Table 2 and 3 (full report), which were based on routes directly comparable among years (i.e., unaltered routes with few or no missing survey years).

Figure 2. Rangewide index of ring-necked pheasants (A) and gray partridge (B) seen per 100 miles driven. Does not include the Northwest region. Based on all survey routes completed.

Figure 3. Rangewide index of eastern cottontail (A) and white-tailed jackrabbits (B) seen per 100 miles driven. Does not include the Northwest region. Based on all survey routes completed.

Figure 4. Rangewide index of white-tailed deer (A) and mourning doves (B) seen per 100 miles driven. Doves were not counted in 1967 and the dove index does not include the Northwest region. Based on all survey routes completed.

# Monitoring Population Trends Of White-Tailed Deer In Minnesota's Farmland/Transition Zone - 2006 

Marrett D. Grund, Farmland Wildlife Populations and Research Group

## INTRODUCTION

White-tailed deer (Odocoileus virginianus) represent one of the most important big game mammals in Minnesota. Although viewed as being important by both hunters and non-hunters, deer also pose socioeconomic and ecological challenges for wildlife managers, such as deer-vehicle collisions, crop depredation, and forest regeneration issues. Thus, monitoring the status of deer populations is critical so that appropriate harvest levels can be determined based on established management goals.

This document: 1) identifies where the farmland population model was applied to model deer population dynamics in Minnesota, 2) describes the structure of and data inputs for the farmland population model, 3) discusses general trends of deer density and current abundance, and 4) describes trends of harvest patterns in the farmland/transition zone.

## METHODS

## Minnesota Farmland/Transition Zone

There were 4 deer management units (DMUs) in Minnesota's farmland/transition zone (Figure 1) and DMUs were further partitioned into deer management sub-units (DMSUs; Figure 2). The primary purpose of DMUs was to pool data in homogeneous landscape types. Permit areas (PAs) delineated within DMUs served as the basis for population modeling and managing antlerless harvests (Figure 3). There were 86 PAs in Minnesota’s farmland zone in 2005. However, the 2 PAs encompassing the Twin Cities metro region were not modeled. Over the past year, there were 9 PAs in northwest Minnesota changed from Zone 4 to Zone 2, and PA 205 changed from Zone 2 to Zone 1. These PAs were renamed to reflect their respective zones. As a result of some PA changes, deer herd dynamics in PAs 105 and 241 are now modeled by the Forest Research Group rather than the Farmland Research Group.

## Population Modeling

The population model used to analyze past trends and test harvest strategies can best be described as an accounting procedure that subtracts losses, adds gains, and keeps a running total of the number of animals alive in various sex-age classes during successive periods of the annual cycle. The deer population is partitioned into 4 sex-age classes (fawns, adults, males, and females). The 12-month year is divided into 4 periods representing important biological events in the deer's life (hunting season, winter, reproduction, and summer). The primary purposes of the farmland model were to: 1) organize and synthesize data on farmland deer populations, 2) advance the understanding of each deer population through population analysis, 3) provide population estimates and simulate vital rates for farmland deer populations, and 4) assist our management efforts through simulations, projections, and predictions of various management prescriptions.

The three most important parameters within the model reflect the aforementioned biological events, which include reproduction, harvest, and non-hunting mortality. Embryo rates were typically estimated at the DMU level via fetal surveys conducted each spring (for details, see Dunbar 2005). Embryo rates were then used to estimate population reproductive rates for each deer herd within a particular DMU. The deer population increased in size after reproduction was simulated. Non-hunting mortality rates occurring during summer months (prior to the hunting season) are estimated from field studies conducted in Minnesota and other agricultural regions. Although summer mortality rates were low, they did represent a reduction in the annual deer population. In farmland deer herds, virtually all mortality occurring during the 12 -month year can be attributed to hunter harvests. Annual harvests were
simulated in the model by subtracting the numerical harvest (adjusted for crippling and non-registered deer) from the pre-hunt population for each respective sex-age class. In heavily hunted deer populations, like those in the farmland/transition region, the numerical harvest data "drive" the population model by substantially reducing the size of the deer herd. Winter mortality rates were estimated from field studies conducted in Minnesota and other farmland regions, similar to summer mortality. After winter mortality rates were simulated, the population was at its lowest point during the 12-month period and the annual cycle began again with reproduction.

## Model Recalibration Efforts

Previous research demonstrated this model provides reliable population estimates if the model is recalibrated every $4-5$ years using field surveys (Grund and Woolf 2004). Thus, efforts began in 2004 to obtain population estimates using aerial and ground surveys. See Grund et al. (2005) and Haroldson et al. (2005) for more details about these surveys. Fifteen PAs have been surveyed over the past 2 years (Table 1). Several PAs have been surveyed using both techniques due to concurrent studies. Preliminary estimates from both techniques have been useful to recalibrate models. However, additional research needs to be conducted to refine field protocols and produce more precise population estimates.

## Population Trends and Densities

Deer densities continue to increase throughout most of the farmland/transition zone. Deer densities were highest in the Big Woods DMU, lowest in the Prairie DMU, and at intermediate levels in the Northwest (Agassiz \& Red River DMUs). Detailed long-term trends in deer densities can be reviewed in Table 2.

In northwestern Minnesota, simulated deer densities indicate a slight downward trend over the last couple of years. Efforts to reduce deer in this area may be having an impact. However, most managers and constituent groups indicate there are still too many deer in northwestern Minnesota.

In the Big Woods DMU, which incorporates the transition zone, deer densities continue to increase. Rate of increase is most rapid in the Southeast and Metro DMSUs, despite efforts to reduce deer populations in these areas.

In the Prairie DMU, deer densities have increased slowly over the last couple of years. Rate of increase is fastest in the North and Southwest DMSUs. This trend reflects objectives and management strategies of most wildlife managers in southwestern Minnesota who wish to either maintain or slightly increase deer herds in their respective work areas.

## Harvest Trends

In northwestern Minnesota, registered harvest densities have steadily increased over the past 5-6 years. Harvest densities are higher and have increased at a faster rate in the Agassiz DMU than in the Red River DMU.

In the Big Woods DMU, harvest densities vary across DMSUs and across years. Trends in harvest densities have been most stable in the Metro and most variable in the Southeast DMSU. Harvest densities have generally increased in the Central and North DMSUs over the past 4-6 years.

In the Prairie DMU, harvest densities have declined in the River DMSU but have been relatively
stable in North and Southwest DMSUs. Harvest densities have fluctuated in the Southeast DMSU but are comparable to harvest densities a decade ago.

# Fetus Survey Data Results Of White-Tailed Deer In The Farmland/Transition Zone Of Minnesota - 2006 

Emily Dunbar, Farmland Populations and Research Group

## INTRODUCTION

Fetus surveys are used to gather information on productivity (number of fetuses per doe) of juvenile ( $\leq 12$ months of age) and adult ( $>12$ months of age) female white-tailed deer (Odocoileus virginianus) in the farmland/transition zone of Minnesota (Figure 1). These data, along with other biological information, are incorporated into the farmland deer population model. The farmland deer population model is used to simulate herd dynamics, predict changes in population size, and determine deer management strategies for 85 permit areas.

A simple and effective method for estimating productivity rates is through direct examination of the reproductive tracts of female deer killed by motor vehicles. The objectives of this survey were to estimate 1) pregnancy rates of juvenile and adult white-tailed deer in the farmland/transition zone of Minnesota and 2) fetal rates of adult and juvenile white-tailed deer in the farmland/transition zone of Minnesota.

## METHODS

Reproductive data required for the farmland deer population model include age class of the female, pregnancy status, number of fetuses present, and gender of the fetuses. These data are collected annually from road-killed females from 1 February to 31 May. Personnel participating in the survey include all wildlife staff in the farmland/transition zone. Area Wildlife Managers are encouraged to contact local Department of Transportation staff and law enforcement officials to facilitate locating dead deer in a timely fashion. Where possible, the use of volunteers is also encouraged.

Equipment for data collection included a sharp knife or scalpel, vinyl gloves, and self-addressed, postagepaid postcards. When examining deer, staff located and opened the uterus to check for fetuses. Staff recorded pregnancy/lactation status, age class of the female, number and gender of all fetuses present, and the location of the road-killed animal (Figure 2). Notes on body condition or any other unusual observations were also recorded.

## RESULTS \& DISCUSSION

A total of 116 deer were examined in 2006. Thirteen (11\%) of these deer came from the Northwest Deer Management Unit (DMU; Table 1), 85 (73\%) from the Big Woods DMU (Table 2), and 18 (16\%) from the Prairie DMU (Table 3).

Pregnancy rates for fawns ranged from $0 \%$ in the Prairie DMU to $41 \%$ in the Big Woods DMU. Throughout the farmland/transition zone, $36 \%$ of fawns were pregnant. Pregnancy rates for adults ranged from $94 \%$ in the Prairie DMU to $100 \%$ in the Northwest DMU and averaged $97 \%$ across the farmland/transition zone.

Fetal rates for fawns ranged from 0.0 fetuses/fawn in the Prairie DMU to 0.5 fetuses/fawn in the Big Woods and Northwest DMUs, and averaged 0.4 fetuses/fawn across the farmland/transition zone. Fetal rates for adults ranged from 1.8 fetuses/adult in the Big Woods to 2.0 fetuses/adult in the Northwest DMU. Fetal rates averaged 1.8 fetuses/adult throughout the farmland/transition zone.

## WILDLIFE DAMAGE COMPLAINTS

NOTE: Wildlife damage complaint information is collected statewide from wildlife managers. The data is compiled and summarized by the Wildlife Damage Extension Specialist at the Brainerd area office.

# WILDLIFE DAMAGE COMPLAINTS <br> Nick Reindl, Wildlife Damage Extension Specialist <br> Steve Benson, Wildlife GIS Coordinator 

Wildlife damage complaint information is collected statewide from wildlife managers. The 2005 information was compiled by MIS - GIS and summarized by the Wildlife Depredation Specialist, 1601 Minnesota Drive, Brainerd, MN 56401.

Figure 1. Wildlife complaints by species for the year 2005, in Minnesota.

Wildlife managers recorded a total of 649 wildlife complaints in 2005 , down $1 \%$ when compared to the 2004 total of 656 complaints. Three species, black bear, white-tailed deer, and Canada geese account for 548, (84.4\%) of the complaints received (Figure1). Five other species of special interest for wildlife damage; cougar, elk, moose, turkey, and sandhill crane, comprise an additional 33, (5.1 \%) of the recorded complaints. Fourteen species are represented in $68(10.5 \%)$ of the complaints received.

The expenditure for depredation materials during FY05 was \$83,550 (8\% bear, 80\% deer, 12\% goose). The average expenditure for the previous five-year period, 2000-2004, was $\$ 78,880$. During calendar year 2005 materials assistance for permanent deer exclusion fences was provided to seventeen growers; six vegetable, two orchard, three small berry, two tree nursery, one Christmas tree farm, and one hay yard for stored forage. Exclusion techniques included the installation of 12 woven wire and five energized permanent deer fences. Additional technical assistance was provided to the Divisions Wildlife and Forestry for jack pine, white pine, oak, and white cedar regeneration plots. Several different techniques were tried utilizing high-density polypropylene mesh as a physical barrier.

# PREDATOR SCENT POST SURVEY 

## AND <br> WINTER TRACK INDICES

NOTE: This survey is organized and coordinated by the Forest Wildlife Populations and Research Group, 1201 E. Hwy 2, Grand Rapids, MN 55744. Results are presented at this location in the book because of the statewide nature of the data.

# Furbearer Winter Track Survey Summary, 2005 

John Erb, Forest Wildlife Populations and Research Group

## INTRODUCTION

Monitoring the distribution and abundance of carnivores can be important for documenting the effects of harvest, habitat change, and environmental variability on these populations. However, many carnivores are highly secretive, difficult to repeatedly capture, and naturally occur at low to moderate densities, making it difficult to estimate abundance over large areas using traditional methods (e.g., markrecapture, distance sampling, etc.). Hence, indices of relative abundance are often used to monitor such populations over time (Hochachka et al. 2000, Wilson and Delahay 2001, Conn et al. 2004).

In winter, tracks of carnivores are readily observable following snowfall. Starting in 1991, Minnesota initiated a carnivore snow track survey in the northern portion of the State. The survey's primary objective is to use a harvest-independent method to monitor distribution and population trends of fisher and marten, 2 species for which no other survey data was available. Because sign of other carnivores is readily detectable in snow, participants also record tracks for other selected species. After 3 years of evaluating survey logistics, the survey became operational in 1994.

## METHODS

Presently, 52 track survey routes are distributed across the northern portion of the state (Figure 1). Each route is 10 miles long, and follows secondary roads or trails. Route locations were subjectively determined based on availability of suitable roads/trails, but were chosen, where possible, to represent the varying forest habitat conditions in northern Minnesota. For data recording, each 10-mile route is divided into 200.5 -mile segments.

Each route is surveyed once following a fresh snow typically from December through midFebruary, and track counts are recorded for each 0.5 -mile segment. When it is obvious the same animal crossed the road multiple times within a 0.5 -mile segment, the animal is only recorded once. If it is obvious that an animal ran along the road and entered multiple 0.5 mile segments (which often occurs with canids), its' tracks are recorded in all segments, but circled to denote it was the same animal. While such duplicate tracks are not included in calculation of track indices (see below), recording data in this manner allows for future analysis of animal activity in relation to survey 'plot' size and habitat. Snowshoe hare are recorded only as present or absent in the first 0.1 miles of each 0.5 -mile segment. While most routes are surveyed 1 day after the conclusion of a snowfall (ending by $6: 00 \mathrm{pm}$ ), thereby allowing 1 night for track 'registry', a few routes are completed 2 or more nights following snowfall. In such cases, track counts on those routes are divided by the number of days post-snowfall.

Currently, 3 summary statistics (2 graphs) are presented for each species. First, I compute the percentage of 0.5 -mile segments with species presence after removing any duplicates (e.g., if the same fox clearly traverses 2 adjacent 0.5 -mile segments along the road, and it was the only 'new' fox in the second segment, only 1 of the 2 segments is considered independently occupied). In addition to this metric, but on the same graph, the average number of tracks per 10 -mile route is presented after removing any obvious duplicate tracks across segments. For wolves traveling through adjacent segments, the maximum number of pack members recorded in any 1 of those segments is used as the track total for that particular group, though this is likely an underestimate of true pack size. Because individuals from many of the species surveyed tend to be solitary, these 2 indices will often yield mathematically equivalent results (i.e., on average, one tends to differ from the other by a constant factor). In the case of wolf packs, and to a lesser extent fox and coyotes which may start traveling as breeding pairs in winter, the approximate equivalence of these 2 indices will still be true if average (detected) group sizes are similar
across years. However, the solitary tendencies in some species are not absolute, potential abundance (in relation to survey plot size) varies across species, and for wolves, pack size may vary annually. For these reasons, as well as to provide an intuitive count metric, both indices are currently presented. Because snowshoe hares are tallied only as present/absent, the 2 indices will by definition be equivalent. Hare survey data is also obtained via counts of animals observed on grouse drumming count surveys conducted in spring. Data for both the spring and winter indices are presented for comparison.

In the second graph, I illustrate the percentage of routes where each species was detected (hereafter, the 'distribution index'). This measure is computed to help assess whether notable changes in the above track indices are a result of larger-scale changes in distribution (more/less routes with presence) and/or finer-scale changes in density along routes.

## RESULTS

Forty-three of the 52 routes were completed this year (Figure 2). Total snow depths averaged 11 " for completed routes, with surveys taking an average of 2.1 hours to complete. Survey routes were completed between Nov. $30^{\text {th }}$ and Feb. $23^{\text {rd }}$ this year.

Following last year's notable decline, fisher track indices increased moderately but remain below recent peaks (Figure 3). Fisher were detected on $67 \%$ of the routes, similar to previous years (Figure 3). For marten, track counts declined slightly compared to last year, with some suggestion of a slow but longer-term decline as well (Figure 3). Marten were detected on $53 \%$ of survey routes, within the bounds of previous results.

Bobcat indices have undergone the most notable change since the survey began. While tracks counts declined moderately this year, they remain above those observed prior to 1999 (Figure 3). Wolf track indices increased slightly from last year (Figure 3), with track indices suggestive of a slow increase since the survey began. Following an upswing through 1999, track indices for red fox subsequently declined (Figure 3), remaining stable in recent years. They remain one of the most ubiquitous species recorded on the survey. Coyote track indices have fluctuated periodically, but with no long-term trends (Figure 3). Weasel track indices declined to their lowest level, but are best characterized as stable, with occasional 'irruptions' in density on occupied routes (Figure 3). Based on known cyclic patterns, snowshoe hare indices have been expected to decline, but they have yet to exhibit a multi-year cyclic decline (Figure 3).

## DISCUSSION

Reliable interpretation of changes in track survey results is dependent on the assumption that the probability of detecting animals remains relatively constant across years (Gibbs 2000). Because this remains an untested assumption, caution is warranted when interpreting changes, particularly annual changes of low to moderate magnitude, or short-term trends.

While we have not yet computed confidence intervals on winter track indices, it is unlikely that any of this year's observed changes were statistically significant. Because electronic data entry for all previous years is now complete, confidence intervals can be computed and should be available by next year. We are also reviewing the adequacy of survey route sample size and distribution, and possible approaches for estimating, and hence correcting for, any differences in the probability of detecting animals across years (e.g., MacKenzie et al. 2004).

While there is some indication of a slow decline in marten indices since 1994, it is possible that the decline in the percentage of routes occupied by marten (Figure 3), particularly from 1995-2000, may be a result of a disproportionate number of new routes being added that were outside current marten range. A more detailed analysis of this possibility is underway.

## ACKNOWLEDGEMENTS

I wish to thank all those who participated in this year's survey, including DNR field staff, numerous tribal participants from the Fond du Lac, Leech Lake, Red Lake, and Grand Portage Bands, and the 1854 Authority.

# Predator/Furbearer Scent Station Survey Summary, 2005 

John Erb, Forest Wildlife Populations and Research Group

## INTRODUCTION

Monitoring the distribution and abundance of carnivores can be important for documenting the effects of harvest, habitat change, and environmental variability on these populations. However, many carnivores are highly secretive, difficult to repeatedly capture, and naturally occur at low to moderate densities, making it difficult to estimate abundance over large areas using traditional methods (e.g., markrecapture, distance sampling, etc.). Hence, indices of relative abundance are often used to monitor such populations over time (Hochachka et al. 2000, Wilson and Delahay 2001, Conn et al. 2004).

In the early 1970 's, the U.S. Fish and Wildlife Service initiated a carnivore survey designed primarily to monitor trends in coyote populations in the western U.S. (Linhart and Knowlton 1975). In 1975, the Minnesota DNR began to utilize similar survey methodology to monitor population trends for numerous terrestrial carnivores within the state. This year marks the $30^{\text {th }}$ anniversary of the carnivore scent station survey.

## METHODS

Scent station survey routes are composed of tracking stations ( 0.9 m diameter circle) of sifted soil with a fatty-acid scent tab placed in the middle. Scent stations are spaced at 0.5 km intervals on alternating sides of a road. During the initial years (1975-82), survey routes were 23.7 km long, with 50 stations per route. Stations were checked for presence/absence of tracks on 4 consecutive nights (old tracks removed each night), and the mean number of station visits per night was the basis for subsequent analysis. Starting in 1983, following suggestions by Roughton and Sweeny (1982), design changes were made whereby routes were shortened to $4.3 \mathrm{~km}, 10$ stations/route (still with 0.5 km spacing between stations), and routes were surveyed only once on the day following route placement. The shorter routes and fewer checks allowed for an increase in the number and geographic distribution of survey routes. In either case, the design can be considered two-stage cluster sampling.

Survey routes were selected non-randomly, but with the intent of maintaining a minimum 5 km separation between routes, and encompassing the variety of habitat conditions within the work area of each survey participant. Most survey routes are placed on secondary (unpaved) roads/trails, and are completed from September through October. Survey results are currently stratified based on 3 'habitat zones' within the state (forest, farmland, and transition).

Track presence/absence is recorded at each station, and track indices are computed as the percentage of scent stations visited by each species. Confidence intervals (95\%) are computed using bootstrap methods (percentile method; Thompson et al. 1998). For each of 1000 replicates, survey routes are randomly re-sampled according to observed zone-specific route sample sizes, and station visitation rates are computed for each replicate sample of routes. Replicates are ranked according to the magnitude of the calculated index, and the $25^{\text {th }}$ and $975^{\text {th }}$ values constitute the lower and upper bounds of the confidence interval. Pre-2001 data has not been electronically entered, so confidence intervals are not yet available for those years. When all data is electronically available, I will be considering the recommendations provided by Sargeant et al. (1998, 2003), particularly the value of utilizing route, rather than station, visitation rates. In addition, we continue to evaluate the merits of re-stratifying analysis based on ecological sections rather than the current 3-zone system.

## RESULTS AND DISCUSSION

A total of 324 routes were completed this year (Figure 1). There were 3,055 operable scent stations examined on the 3244.3 km routes. Route density varied from $1 / 500 \mathrm{~km}^{2}$ in the Forest Zone to $1 / 1,155 \mathrm{~km}^{2}$ in the Farmland (Figure 1).

For the first time in many years, red fox were no longer the most frequently detected species across routes. Statewide, route visitation rates (\% of routes with detection) were highest for skunk (38\% of all routes), followed by raccoon and domestic cat (35\%), red fox (34\%), dog (19\%), and coyote (18\%). Regionally, route visitation rates were as follows: red fox - Farmland (FA) 24\%, Transition (TR) 26\%, Forest (FO) 42\%; coyote - FA 41\%, TR 14\%, FO 13\%; skunk - FA 63\%, TR 47\%, FO 24\%; raccoon FA $68 \%$, TR $48 \%$, FO 16\%; domestic cat - FA $54 \%$, TR $55 \%$, FO $17 \%$; and dog - FA $34 \%$, TR 30\%, FO $7 \%$. Figures $2-5$ show station visitation indices (\% of stations visited) from the survey's inception through the current year.

Although the survey is largely intended to document long-term trends in populations, confidence intervals improve interpretation of the significance of annual changes. Based on the presence/absence of interval overlap, the only significant change from last year was an increase in raccoon indices in the farmland zone. This follows a significant decrease observed last year.

Point estimates for red fox indices in the farmland and transition zones continue their steady decline that began in 1990 (Figure 2 and 3), while coyote indices continue to steadily increase (farmland zone only). Farmland raccoon indices increased for 15 years, then generally declined for 7 , but significantly increased this year (Figure 2). In general, indices for most other species/zones have fluctuated but have not exhibited any notable long-term trends.

## ACKNOWLEDGEMENTS

I wish to thank all of the cooperators who participated in the 2005 survey: DNR Division of Wildlife staff; Superior National Forest; Agassiz, Rydell, Sherburne, Tamarac, and Minnesota Valley National Wildlife Refuges; USFWS Wetland Management Districts; White Earth, Red Lake, and Leech Lake Reservations; 1854 Authority; Vermillion Community College; Beltrami and Cass County Land Departments; Marshall County Central High School; St. Croix National Scenic Waterway; and Richard Nelles and Tom Stuber.

# Grouse Surveys in Minnesota During Spring 2006 

Michael A. Larson, Forest Wildlife Populations and Research Group

## SUMMARY OF FINDINGS

Surveys for ruffed grouse (Bonasa umbellus), sharp-tailed grouse (Tympanuchus phasianellus), and greater prairie-chickens (Tympanuchus cupido pinnatus) were conducted during April and May 2006. Mean counts of ruffed grouse drums throughout the forested regions of Minnesota were 1.0 (95\% confidence interval $=0.9-1.1$ ) drums/stop (dps). That was significantly greater than the 0.8 ( $0.7-0.9$ ) dps observed during 2005 and similar to counts from 2001.

During the spring 2006 survey 1,463 sharp-tailed grouse were observed at 159 dancing grounds. The mean number of sharp-tailed grouse per dancing ground was 8.2 (6.9-9.7) in the East Central survey region, 9.9 (8.7-11.1) in the Northwest region, and 9.2 (8.3-10.1) statewide. Index values in the Northwest and statewide were significantly less during 2006 than during 2005, but the statewide index value was near the most recent 20-year mean.

We counted 1,766 male prairie-chickens and located 152 booming grounds. Within survey blocks we observed 0.29 leks $/ \mathrm{mi}^{2}\left(0.11\right.$ leks $/ \mathrm{km}^{2}$ ) and 13.9 males/lek. Approximately $21 \%$ fewer males and $18 \%$ fewer leks were counted in survey blocks during spring 2006 than during spring 2005. Densities observed during 2006, however, were greater than the means observed for 1993-2002.

## INTRODUCTION

## Index Surveys

The purpose of surveys of grouse populations in Minnesota is to monitor changes in the densities of grouse over time. Estimates of density, however, are difficult and expensive to obtain. Simple counts of animals, on the other hand, are convenient and, assuming that changes in density are the major source of variation in counts among years, they can provide a reasonable index to long-term trends in populations. Other factors, such as weather and habitat conditions, observer ability, and grouse behavior, vary over time and also affect simple counts of animals. These other factors make it difficult to make inferences about potential changes in wildlife populations over short periods of time (e.g., a few annual surveys) or from small changes in index values. Over longer periods of time or when changes in index values are large, assumptions upon which grouse surveys in Minnesota depend are more likely to be valid, thereby making inferences about grouse populations more valid. For example, index values from the ruffed grouse drumming count survey have documented what is believed to be true periodic fluctuations in ruffed grouse densities (i.e., the 10-year cycle).

## Ruffed Grouse

The ruffed grouse (Bonasa umbellus) is Minnesota's most popular game bird. It occurs throughout the forested regions of the state. Annual harvest varies from approximately 150,000 to 1.4 million birds and averages $>500,000$ birds. Information derived from spring drumming counts and hunter harvest statistics indicates that ruffed grouse populations fluctuate cyclically at intervals of approximately 10 years.

During spring there is a peak in the drumming behavior of male ruffed grouse. Ruffed grouse drum to communicate to other grouse the location of their territory. The purpose is to attract females for breeding and deter encroachment by competing males. Drumming makes male ruffed grouse much easier to detect, so counts of drumming males is a convenient basis for surveys to monitor changes in the densities of ruffed grouse. Ruffed grouse were first surveyed in Minnesota during the mid-1930s. Spring drumming counts have been conducted annually since the establishment of the first survey routes in 1949.

## Sharp-tailed Grouse

Sharp-tailed grouse (Tympanuchus phasianellus) in Minnesota occur in brushlands, which often form transition zones between forests and grasslands. Sharp-tailed grouse are considered a valuable indicator of the availability and quality of brushlands for wildlife. Although sharp-tailed grouse habitat was more widely distributed in Minnesota during the early- and mid-1900s, the range of sharp-tailed grouse is now limited to areas in the Northwest (NW) and East Central (EC) portions of the state (Figure 1). Since 1990 annual harvest of sharp-tailed grouse by hunters has varied from 8,000 to 30,000 birds, and the number of hunters has varied from 6,000 to 13,000 .

During spring male sharp-tailed grouse gather at dancing grounds, or leks, in grassy areas where they defend small territories and make displays to attract females for breeding. Surveys of sharp-tailed grouse populations are based on counts of grouse at dancing grounds. The first surveys of sharp-tailed grouse in Minnesota were conducted between the early 1940s and 1960. The current sharp-tailed grouse survey was initiated in 1976.

## Greater Prairie-Chickens

During the early 1800s greater prairie-chickens (Tympanuchus cupido pinnatus) were present along the southern edge of Minnesota. Their range expanded and contracted dramatically during the next 150 years. Currently, most prairie-chickens in Minnesota occur along the beach ridges of glacial Lake Agassiz in the west (Figure 1). The population of prairie-chickens there was expanded southward to the upper Minnesota River valley by a series of relocations during 1998-2005. Hunters in Minnesota have harvested approximately 100 prairie-chickens annually since 2003 when a limited-entry hunting season was opened for the first time since 1942.

Like sharp-tailed grouse, prairie-chickens gather at leks during spring. The leks of prairiechickens are also called booming grounds because males make a low-frequency, booming vocalization during their displays. From 1974 to 2003 the Minnesota Prairie Chicken Society coordinated annual counts of prairie-chickens. During 2004 the Minnesota Department of Natural Resources (DNR) began coordinating the annual prairie-chicken surveys, and a standardized survey design was adopted.

## METHODS

## Ruffed Grouse

Roadside routes consisting of 10 semipermanent stops approximately 1.6 km (1 mile) apart have been established. Routes were originally located along roads with little automobile traffic that were also near apparent ruffed grouse habitat. Therefore, route locations were not selected according to a statistically valid spatial sampling design, which means that data collected along routes is not necessarily representative of the larger areas (e.g., counties, regions) in which routes occur. Approximately 50 routes were established by the mid-1950s, and approximately 70 more were established during the late-1970s and early-1980s.

Observers from the Department of Natural Resources (DNR) Area Wildlife Offices and a variety of other organizations drove along each survey route once just after sunrise during April or May. Observers were not trained but often were experienced with the survey. At each designated stop along the route the observer listened for 4 minutes and recorded the number of ruffed grouse drums (not necessarily the number of individual grouse) he or she heard. Attempts were made to conduct surveys on days near the peak of drumming activity that had little wind and no precipitation.

The survey index value was the number of drums heard during each stop along a route. The mean number of drums/stop (dps) was calculated for each of 4 survey regions and for the entire state. To determine regional boundaries, I evaluated Spearman's rank correlations among annual mean drum
counts in the 7 forested sections of the Ecological Classification System (ECS) in Minnesota. Drum counts during the last 2 full cycles of the ruffed grouse population (i.e., 1984-2004) were highly correlated among the 4 sections comprising the Laurentian Mixed Forest province (i.e., Northeast region), which covers the core and bulk of the range of ruffed grouse in Minnesota (Figure 2). Apparent longterm population dynamics were noticeably different and correlations were lower for the other 3 ECS sections (i.e., Northwest, Southwest, and Southeast regions), which are along the periphery of ruffed grouse range. The new survey regions are similar to the traditional ruffed grouse zones. The Southeast region and zone are identical, the Southwest region is analogous to the Central Hardwoods zone, the Northwest region consists of the western half of the Northwest zone, and the Northeast region includes the Northeast and North Central zones (Figure 2).

As an intermediate step to summarizing survey results by region, I calculated the mean number of dps for each route. Mean index values for survey regions were calculated as the mean of route-level means for all routes occurring within the region. Some routes crossed regional boundaries, so data from those routes were included in the means for both regions. The number of routes within regions was not proportional to any meaningful characteristic of the regions or ECS section upon which they were based. Therefore, mean index values for the Northeast region and the state were calculated as the weighted mean of index values for the 4 and 7 ECS sections, respectively, they included. The weight for each section mean was the geographic area of the section (i.e., AAP $=11,761 \mathrm{~km}^{2}$, $\mathrm{MOP}=21,468 \mathrm{~km}^{2}, \mathrm{NSU}=24,160$ $\mathrm{km}^{2}, \mathrm{DLP}=33,955 \mathrm{~km}^{2}$, WSU $=14,158 \mathrm{~km}^{2}, \mathrm{MIM}=20,886 \mathrm{~km}^{2}$, and $\mathrm{PP}=5,212 \mathrm{~km}^{2}$; see Figure 2 caption for full section names). Only approximately half of the Minnesota and Northeast Iowa Morainal (MIM) and Paleozoic Plateau (PP) sections were within the ruffed grouse range, so the area used to weight drum index means for those sections was reduced accordingly using subsection boundaries.

Stops along survey routes are a small sample of all possible stops within the range of ruffed grouse in Minnesota. Survey index values based on the sample of stops are not the same as they would be if drum counts were conducted at a different sample of stops or at all possible stops. To account for the uncertainty in index values because they are based on a sample, I calculated $95 \%$ confidence intervals (CI) for each mean. A $95 \%$ confidence interval is a numerical range in which $95 \%$ of similarly estimated intervals (i.e., from different hypothetical samples) would contain the true, unknown mean. I used 10,000 bootstrap samples of route-level means to estimate percentile CIs for mean index values for survey regions and the whole state. Limits of each CI were defined as the $2.5^{\text {th }}$ and $97.5^{\text {th }}$ percentiles of the bootstrap frequency distribution.

I calculated mean index values and CIs for 1982-2006. Data from earlier years were not analyzed because they were not available in a digital form.

## Sharp-tailed Grouse

Over time, DNR Wildlife Managers have recorded the locations of sharp-tailed grouse dancing grounds in their work areas. As new dancing grounds were located, they were added to the survey list. Known and accessible dancing grounds were surveyed by Wildlife Area staff and their volunteers between sunrise and 2.5 hours after sunrise during April and early-May to count sharp-tailed grouse. When possible, surveys were conducted when the sky was clear and the wind was $<16 \mathrm{~km} / \mathrm{hr}$ ( 10 mph ). Attempts were made to conduct surveys on $>1$ day to account for variation in the attendance of male grouse at the dancing ground. Survey data consist of the maximum of daily counts of sharp-tailed grouse at each dancing ground.

The dancing grounds included in the survey were not selected according to a statistically valid spatial sampling design. Therefore, data collected during the survey was not necessarily representative of the larger areas (e.g., counties, regions) in which the dancing grounds occur. It was believed, however,
that most dancing grounds within each work area were included in the sample, thereby minimizing the limitations caused by the sampling design.

I calculated the mean number of sharp-tailed grouse per dancing ground (i.e., index value), averaged across dancing grounds within the NW and EC regions and statewide for spring 2006. The number of grouse included those recorded as males and those recorded as being of unknown sex. It was not valid to compare the full survey data and results from different years because survey effort and success in detecting and observing sharp-tailed grouse was different between years and the survey samples were not necessarily representative of other dancing grounds. To estimate differences in sharptailed grouse index values between 2 years, therefore, I analyzed separately sets of data that included counts of birds only from dancing grounds that were surveyed during both years. Although the dancing grounds in the separate data sets were considered comparable, the counts of birds at the dancing grounds still were not. Many factors can affect the number of birds counted, so inferences based upon comparisons of survey data between years are tenuous. I used a separate data set of comparable leks to calculate the mean difference in the number of birds counted per dancing ground between 2005 and 2006.

I ran a similar analysis for survey data from 2004 and 2005, including calculating mean index values and differences between years, because there was an error in the results I presented in the 2005 Grouse Survey Report. I had not removed dancing grounds with <2 male grouse before calculating the means, so the reported index values were less than they should have been. For example, although observers counted 1,824 grouse while visiting 193 lek sites, only 1,818 grouse were observed at the 161 leks with $\geq 2$ males (i.e., a conservative definition of a dancing ground).

To account for the uncertainty in index values because they are based on a sample of dancing grounds rather than all dancing grounds, I calculated 95\% confidence intervals (CI) for each mean. I used 10,000 bootstrap samples of dancing ground counts to estimate percentile confidence intervals for mean index values for the NW and EC regions and the whole state.

The current delineation between the NW and EC survey regions was based on ECS section boundaries (Figure 1), with the NW region consisting of the Lake Agassiz \& Aspen Parklands and Northern Minnesota \& Ontario Peatlands sections and the EC region consisting of selected subsections of the Northern Minnesota Drift \& Lake Plains, Western Superior Uplands, and Southern Superior Uplands sections. The 2005 Grouse Survey Report detailed the transition from the former to the current delineation of regions.

## Greater Prairie-Chickens

During the few hours near sunrise from late-March until mid-May cooperating biologists and numerous volunteers counted prairie-chickens at leks in western Minnesota. They attempted to locate and observe multiple times all prairie-chicken leks within 17 designated survey blocks (Figure 3). Each block was approximately 4 miles $\times 4$ miles square ( $4,144 \mathrm{ha}$ ) and was selected nonrandomly based upon the spatial distribution of leks and the presence of relatively abundant grassland habitat. Ten survey blocks were located in what was considered the core of the prairie-chicken range in Minnesota. The other 7 blocks were located in the periphery of the range. The permit areas for the fall hunting season roughly coincide with the core of the range (Figure 3).

Observations of leks outside the survey blocks were also recorded. They contribute to the known minimum abundance of prairie-chickens and may be of historical significance. These observations, however, were only incidental to the formal survey. Bird counts from areas outside the survey blocks cannot be used to make inferences about the relative abundance of prairie-chickens among different geographic areas (e.g., counties, permit areas) or points in time (e.g., years) because the amount of effort expended to obtain the observations was not standardized or recorded.

Observers counted prairie-chickens at leks from a distance using binoculars. If vegetation or topography obscured the view of a lek, the observer attempted to flush the birds to obtain an accurate count. Observed prairie-chickens were classified by sex as either male, female, or unknown. Male prairie-chickens were usually obvious due to their display behavior. Birds were classified as unknown sex when none of the birds at a lek were observed displaying or when the birds had to be flushed to be counted. Most birds classified as unknown likely were males because most birds at leks are males. Although most male prairie-chickens attend leks most mornings, female attendance at leks is much more limited and sporadic. Females are also more difficult to detect because they do not vocalize or display like males. Counts of males and unknowns, rather than females, therefore, were used to make comparisons between core and peripheral ranges and between years.

## RESULTS \& DISCUSSION

## Ruffed Grouse

Observers from 16 cooperating organizations surveyed 128 routes between 9 April and 19 May 2006. Most routes ( $87 \%$ ) were run between 20 April and 8 May. Cooperators included the DNR Divisions of Fish \& Wildlife and Ecological Services; Chippewa and Superior National Forests (USDA Forest Service); Fond du Lac, Grand Portage, Red Lake, and White Earth Reservations; Agassiz and Tamarac National Wildlife Refuges (U.S. Fish \& Wildlife Service); Central Lakes College and Vermilion Community College; Beltrami and Cass County Land Departments; UPM Blandin Paper Mill; and Gull Lake Recreation Area (U.S. Army Corps of Engineers). Observers reported survey conditions as Excellent, Good, and Fair on $52 \%, 35 \%$, and $13 \%$ of 122 routes, respectively. Survey conditions during 2005 were Excellent, Good, and Fair on $48 \%, 39 \%$, and $12 \%$ of routes, respectively.

Mean counts of ruffed grouse drums throughout the forested regions of Minnesota were 1.0 (95\% confidence interval $=0.9-1.1$ ) drums/stop (dps) during 2006. That was similar to counts during 2001 and significantly greater than the $0.8(0.7-0.9)$ dps observed last year (Figure 4). Increases of $0.2-0.3 \mathrm{dps}$ from 2005 means were observed in the Northeast, Northwest, and Southwest regions but not in the Southeast region (Figure 5). Drum counts by survey region were 1.1 (0.9-1.2) dps in the Northeast, 1.0 ( $0.8-1.4$ ) dps in the Northwest, $0.8(0.4-1.2)$ dps in the Southwest, and $0.6(0.2-1.1)$ dps in the Southeast. Median index values for bootstrap samples were similar to observed means, so no bias-correction was necessary.

Based upon the drum count index, ruffed grouse densities throughout most of Minnesota during spring 2006 were likely greater than spring densities during 2004 and 2005. This year, therefore, could mark the beginning of the next cyclical increase in the population. Given the variability in the cycle and uncertainties about the survey results, however, such a conclusion cannot be made until at least next year.

## Sharp-tailed Grouse

A total of 1,463 sharp-tailed grouse was observed at 159 dancing grounds with $\geq 2$ male grouse (or grouse of unknown sex) during spring 2006. The resulting index value was similar to the mean from the last 26 years (Figure 6). Leks with $\geq 2$ grouse were visited a mean of 1.9 times, and 125 historic lek sites with $\leq 1$ male were also surveyed at least once.

The index value in the EC region has remained the same at 8-9 grouse/lek since at least 2004 (Table 1). The index values among comparable leks in the NW region and statewide declined by 3.6 ( $95 \%$ CI $=1.9-5.3$ ) and $2.5(95 \%$ CI = 1.3-3.7) grouse/lek, respectively, between 2005 and 2006. Somewhat smaller declines also occurred in the NW and statewide between 2004 and 2005, despite annual means that increased slightly that year. The apparent paradox was caused by differences in the leks included in each annual data set compared to the set of "comparable" leks. The discrepancies
highlight the problems with making inferences from samples that cannot be assumed to be representative of the population of interest.

Table 1. Number of sharp-tailed grouse observed per dancing ground in Minnesota during spring.

| Year ${ }^{\text {b }}$ | Statewide |  |  | Northwest ${ }^{\text {a }}$ |  |  | Eastcentral ${ }^{\text {a }}$ |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Mean | 95\% CI ${ }^{\text {c }}$ | $n^{\text {d }}$ | Mean | 95\% CI ${ }^{\text {c }}$ | $n^{\text {d }}$ | Mean | 95\%CI ${ }^{\text {c }}$ | $n^{\text {d }}$ |
| 2004 | 11.2 | 10.1-12.3 | 183 | 12.7 | 11.3-14.2 | 116 | 8.5 | 7.2-9.9 | 67 |
| 2005 | 11.3 | 10.2-12.5 | 161 | 13.1 | 11.5-14.7 | 95 | 8.8 | 7.3-10.2 | 66 |
| 2006 | 9.2 | 8.3-10.1 | 159 | 9.9 | 8.7-11.1 | 95 | 8.2 | 6.9-9.7 | 64 |
| Difference ${ }_{04-05}$ | -1.3 | -2.2--0.3 | 186 | -2.1 | -3.5--0.8 | 112 | 0.0 | -1.0-1.1 | 74 |
| Difference ${ }_{05-06}$ | -2.5 | -3.7--1.3 | 126 | -3.6 | -5.3--1.9 | 70 | -1.1 | -2.6-0.6 | 56 |

${ }^{\text {a }}$ Survey regions; see Figure 1.
${ }^{\mathrm{b}}$ Year or the mean difference between comparable leks during consecutive years.
${ }^{\text {c }} 95 \% \mathrm{CI}=95 \%$ confidence interval for the mean. It is an estimate of the uncertainty in the value of the mean.
${ }^{\mathrm{d}} n=$ number of dancing grounds in the sample.

## Greater Prairie-Chickens

Observers from at least 4 cooperating organizations counted prairie-chickens during spring 2006. Cooperators included the DNR Division of Fish and Wildlife, Fergus Falls and Detroit Lakes Wetland Management Districts (U.S. Fish \& Wildlife Service), University of Minnesota-Crookston, and The Nature Conservancy. Observers located 152 booming grounds and counted 1,766 male prairie-chickens (Table 2). Within hunting permit areas we observed $0.09 \mathrm{leks} / \mathrm{mi}^{2}\left(0.04 \mathrm{leks} / \mathrm{km}^{2}\right)$ and 12.2 males/lek. Minimum counts in Table 2 and the densities calculated from them are not comparable among permit areas or years because they included surveys that were conducted outside of the survey blocks and did not follow a spatial sampling design.

Table 2. Minimum abundance of prairie-chickens within and outside of hunting permit areas in western Minnesota during spring 2006. Counts of leks and birds are not comparable among permit areas or years.

| Permit <br> Area | Area <br> (sq. mi.) | Leks | Males | Unk. $^{\text {a }}$ |
| :---: | ---: | ---: | ---: | ---: |

${ }^{a}$ Unk. = prairie-chickens of unknown sex. It is likely that most were males.
${ }^{\mathrm{b}}$ Sum among the 7 permit areas.
${ }^{\text {c }}$ Counts from outside the permit areas.
${ }^{\mathrm{d}}$ NA = not applicable. The size of the area outside permit areas was not defined.

Each booming ground was observed on a median of 2 (mean = 1.9) different days, but $39 \%$ of leks were observed only once. Attendance of males at prairie-chicken leks varies among days and by time of day. Single counts of males at a booming ground, therefore, may be an unreliable indication of true abundance. Similar counts on multiple days, on the other hand, demonstrate that the counts may be a good indicator of true abundance. Even multiple counts, however, cannot overcome the problems associated with the failure to estimate the probability of detecting leks and individual birds at leks. Without estimates of detection probability, the prairie-chicken survey is an index to, not an estimate of, prairie-chicken abundance within the survey blocks. The credibility of the index for monitoring changes in abundance among years is dependent upon the untested assumption that a linear relationship exists between counts of male prairie-chickens and true abundance. In other words, we assume that (the expected value of) the probability of detection does not change among years.

Within survey blocks we counted 1,110 males (includes birds of unknown sex) on 80 leks (Table 3). That was $21 \%$ fewer males and $18 \%$ fewer leks than were counted in survey blocks during spring 2005. Leks were defined as having $\geq 2$ males, so observations of single males were excluded from summaries by survey block. During spring 2006 we observed 0.35 leks $/ \mathrm{mi}^{2}$ ( $0.13 \mathrm{leks} / \mathrm{km}^{2}$ ) and 15.1 males/lek in survey blocks in the core of the range, whereas we observed 0.21 leks $/ \mathrm{mi}^{2}\left(0.08\right.$ leks $/ \mathrm{km}{ }^{2}$ ) and 11.0 males/lek in peripheral blocks (Table 3). The densities of prairie-chickens observed during 2006 were greater than the means of 0.2 leks $/ \mathrm{mi}^{2}$ and 11.5 males/lek observed in survey blocks from 1993 until 2002.

Table 3. Counts of prairie-chickens within survey blocks in Minnesota.

| Range ${ }^{\text {b }}$ | Survey Block | $\begin{gathered} \text { Area } \\ \left(\text { miles }^{2}\right) \end{gathered}$ | 2006 |  | Change from 2005 ${ }^{\text {a }}$ |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  | Leks | Males ${ }^{\text {c }}$ | Leks | Males ${ }^{\text {c }}$ |
| Core | Polk 2 | 16.2 | 4 | 65 | -5 | -54 |
|  | Norman 1 | 16.1 | 3 | 42 | -2 | 13 |
|  | Norman 3 | 16.0 | 6 | 90 | 1 | 22 |
|  | Clay 1 | 17.6 | 9 | 155 | 1 | 10 |
|  | Clay 2 | 16.0 | 2 | 101 | -1 | -7 |
|  | Clay 3 | 16.1 | 9 | 143 | 0 | -25 |
|  | Clay 4 | 14.9 | 5 | 57 | -1 | -11 |
|  | Wilkin 1 | 15.4 | 9 | 93 | -1 | -87 |
|  | Wilkin 3 | 16.1 | 6 | 71 | 0 | -30 |
|  | Otter Tail 1 | 15.9 | 3 | 30 | 1 | -1 |
|  | Core subtotal | 160.2 | 56 | 847 | -7 | -170 |
| Periphery | Polk 1 | 15.9 | 4 | 48 | -6 | -41 |
|  | Norman 2 | 16.3 | 5 | 62 | -3 | -37 |
|  | Mahnomen | 16.1 | 3 | 48 | -2 | -19 |
|  | Becker 1 | 16.0 | 3 | 24 | -1 | -17 |
|  | Becker 2 | 16.1 | 4 | 42 | 0 | -1 |
|  | Wilkin 2 | 16.1 | 2 | 16 | 0 | -7 |
|  | Otter Tail 2 | 15.7 | 3 | 23 | 1 | -5 |
|  | Periphery subtotal | 112.2 | 24 | 263 | -11 | -127 |
| Grand total |  | 272.4 | 80 | 1,110 | -18 | -297 |

${ }^{\text {a }}$ The 2005 count was subtracted from the 2006 count, so a negative value indicates a decline.
${ }^{\text {b }}$ Survey blocks were classified as either mostly within the hunting permit areas (core) or mostly outside the permit areas (periphery).
${ }^{\text {c }}$ Includes birds recorded as being of unknown sex but excludes lone males not observed at a booming ground.

## ACKNOWLEDGEMENTS

I sincerely appreciate the efforts of all the DNR staff and volunteer cooperators who conducted and helped coordinate the grouse surveys. I also thank Laura Gilbert for helping with data entry and archiving and Mark Lenarz for reviewing an earlier draft of this report.

Figure 1. Northwest (NW) and East Central (EC) survey regions for sharp-tailed grouse (top panel) and primary range of greater prairie-chickens (bottom panel) relative to county boundaries in Minnesota. The sharp-tailed grouse regions were based largely on boundaries of ECS Subsections, whereas the prairie-chicken range was based on ECS Land Type Associations.

Figure 2. Ruffed grouse survey regions (shaded, curved boundaries). Top panel: regions are labeled and overlaid on counties (dashed lines). Bottom panel: former survey zones (straight boundaries) are labeled and overlaid on regions. The northeast (NE) region corresponds to the northeast (NE) and northcentral (NC) zones. It includes the Northern Minnesota \& Ontario Peatlands, Northern Superior Uplands, Northern Minnesota Drift \& Lake Plains, and Western Superior Uplands sections, including a small portion of the Southern Superior Uplands in eastern Carlton County. The northwest (NW) region corresponds to the northwest (NW) zone and consists of the Lake Agassiz \& Aspen Parklands section. The southwest (SW) region is similar to the central hardwoods (CH) zone and consists of the northern half of the Minnesota and Northeast Iowa Morainal section. The southeast (SE) region is identical to the southeast (SE) zone and consists of the eastern half of the Paleozoic Plateau section.

Figure 3. Survey blocks (labeled squares) and hunting permit area boundaries (solid lines) for prairiechickens in western Minnesota. Survey blocks were designated as being in either the core (black) or periphery (gray) of the range. Blocks were named after the counties (dashed lines) in which they were primarily located. Permit areas are ordered from north to south: 405A, 407A, 407B, 407C, 420A, 420B, and 421A.

Figure 4. Ruffed grouse drum count index values in Minnesota (top) and just the Northeast region (bottom). Vertical error bars represent $95 \%$ confidence intervals based on bootstrap samples. Statewide means before 1982 were not re-analyzed with the current methods, so confidence intervals were not available. The difference in index values between 1981 and 1982 reflected a real decrease in drums counted, not an artifact of the change in analysis methods.

Figure 5. Ruffed grouse drum count index values in the Northwest (top), Southwest (middle), and Southeast (bottom) survey regions of Minnesota. Dashed horizontal lines indicate the mean from 1984 to 2004. Vertical error bars represent $95 \%$ confidence intervals based on bootstrap samples. One error bar in the bottom panel was truncated.

Figure 6. Mean number of sharp-tailed grouse observed in Minnesota during spring surveys of dancing grounds. Vertical error bars, which were not calculated for 1980-2003, represent $95 \%$ confidence intervals based on bootstrap samples. No line connects the annual means because they are not based on comparable samples of leks.

# Registered Furbearer Population Modeling 2006 Report 

John Erb, Forest Wildlife Populations and Research Group

## INTRODUCTION

For populations of secretive carnivores, obtaining field-based estimates of population size remains a challenging task (Hochachka et al. 2000; Wilson and Delehay 2001; Conn et al. 2004). This is particularly true when one is interested in annual estimates, multiple species, and/or large areas. Nevertheless, population estimates are desirable to assist in making management/harvest decisions. Population modeling is a valuable tool for synthesizing our knowledge of population demography, predicting outcomes of management decisions, and approximating population size.

In the late 1970s, Minnesota developed population models for 4 species of carnivores (fisher, marten, bobcat, and otter) to help 'estimate' population size and track population changes. All are deterministic 'accounting' models that do not currently incorporate density-dependence. However, juvenile survival adjustments are made for bobcats and fisher during cyclic lows in hare abundance and following severe winters, particularly those where northern deer populations decline. For juvenile marten, survival is adjusted downward during apparent lows in small mammal abundance. Modeling projections are interpreted in conjunction with harvest data and results from annual field-based track surveys, with the exception of otter for which no harvest-independent survey data is currently available for comparison.

## METHODS

Primary model inputs include the estimated 1977 'starting' population size, estimates of agespecific survival and reproduction, and sex- and age-specific harvest data. Reproductive inputs are based largely on carcass data collected in the early 1980s, and for bobcats, additional data collected in 1992 and from 2003-present. Initial survival inputs were based on a review of published estimates in the literature, but are periodically adjusted as noted above. In some cases, parameter adjustments for previous years are delayed until additional data on prey abundance trends is available. Hence, population estimates reported in previous reports may not always match those reported in current reports. Obtaining updated Minnesota-specific survival estimates remains a goal for future research.

Harvest data is obtained through mandatory furbearer registration. A detailed summary of 2004 harvest information is available in a separate report. Bobcat and pine marten year-class data is obtained via a combination of x-ray examination of pulp cavity width and microscopic counts of cementum annuli from teeth of harvested animals. While the population models only utilize data for the 3 age-classes (juvenile, yearling, adult), marten and bobcat cementum annuli counts have been collected for all nonjuveniles in recent years to facilitate interpretation of reproductive data (bobcats) and to obtain current information on year-class distribution for both species. Current harvest age proportions for fisher and otter are approximated using averages computed from carcass collections obtained during 1980-86 (otter) and 1977-1994 (fisher).

For comparison to model projections, field-based track survey indices are presented in this report as running 3 -year ( $\mathrm{t}-1, \mathrm{t}, \mathrm{t}+1$ ) averages of the observed track index, with the most recent year's average computed as ( $2 / 3^{*}$ current index $+1 / 3^{*}$ previous index). More detailed descriptions of scent post and winter track survey methods and results are available in separate reports.

## RESULTS AND DISCUSSION

## Bobcat

The 2005 registered DNR trapping and hunting harvest was 590, down $\sim 6 \%$ from last year's record of 631 (Table 1). Trapping harvest declined $20 \%$, while hunting harvest increased $66 \%$. Modeled harvest, which includes tribal take, was 638 . Based on population modeling estimates, $19 \%$ of the fall population was harvested. The juvenile to adult female ratio in the harvest ( 0.8 ) was on the low end of previously observed values (Table 1), apparently a result of a large proportion of 2 year olds in the harvest (Figure 1). This follows last year's record proportion of yearlings in the harvest.

Based on examination of reproductive tracts, pregnancy rate of yearlings was estimated at $26 \%$, and has ranged from 16 to $51 \%$ the last 3 years. Average litter size for pregnant yearlings was 2.3 . Pregnancy rate for $2+$ year olds averaged $74 \%$, with a mean litter size of 2.9.

Modeling predicts a slow but continued decline in this spring's bobcat population (Figure 2), but the estimated population remains above pre-2001 levels. Averaged winter track counts also declined, but as with population estimates, track counts remain above pre-2001 levels. The estimated 2006 spring population is $\sim 2,400$.

## Fisher

Harvest under the DNR framework was 2,388, down 7\% from last year (Table 2). Modeled harvest was 2,481 . An estimated $21 \%$ of the fisher population was harvested, within the bounds of previous seasons. Carcass collections ended in 1994, so no current age or reproductive data are available. Population modeling suggests a stable to slightly declining fisher population in recent years (Figure 3). Modeling estimates a current spring population of $\sim 8,800$.

## Pine Marten

After 3 years of successive records, marten harvests declined 18\% in 2005 (DNR framework 2,653; modeled harvest $-2,873$ ) (Table 3). Although juveniles clearly predominate in the marten harvest, 'older' marten are evident in the harvest as well (Figure 4). The maximum age observed has declined slightly the last 3 years (13, 12, and 11). Maximum ages from Ontario marten rarely exceed 13 (Fryxell et al. 2001). Based on modeling, $20 \%$ of the fall population was harvested. Following last year's record lows, the percent juveniles (53\%) and the juvenile:adult female ratio (4.9) in the harvest both increased, but remain below averages recorded prior to 2002 (Table 3).

Following 3 years of increased harvest, both modeling and averaged winter track counts suggest the population has been declining, with an estimated spring population of $\sim 11,000$ (Figure 5). Nevertheless, population estimates remain above the long-term average.

## Otter

After successive record harvests, the DNR framework otter harvest declined $18 \%$ to 2,846, and the modeled harvest total was 2,884 (Table 4). An estimated $21 \%$ of the fall population was harvested. Carcass collections ended in 1986, so no age or reproductive data are available. Modeling indicates the population has slightly declined in each of the past 4 years (Figure 6). No independent otter survey data are currently available for comparison. The current estimated spring population is $\sim 10,800$.

# Population Trends of White-Tailed Deer in the Forest Zone, 2006 

Mark S. Lenarz, Forest Wildlife Populations and Research Group

## INTRODUCTION

Deer hunters are required by regulation to register each deer they harvest within 24 hours of the close of the deer-hunting season. Data collected as part of this registration process provide important information on the sex and age of deer killed, population trends, and the effectiveness of current management regulations. The following report presents a brief analysis of the 2005 harvest registration data in the forest zone (Figure 1). This is followed by a discussion of deer population trends and projections in the forest zone based on simulation modeling.

Figure 1. Either-sex permit areas in the forested zone, 2006. Permit areas 114, 152, 182, 287, and Red Lake Indian Reservation were not modeled.

## HARVEST

In 2005, hunters registered 255,736 deer, the third highest harvest ever recorded in Minnesota. Of that number, $51 \%$ or 130,307 deer were harvested in the forested zone (Figure 1, Table 1). The 2005
forest zone harvest declined 7\% from the 2004 harvest. The following discussion applies to the subset of deer harvested in the forest zone.

The buck harvest decreased or remained stable in 39 of the 41 permit areas (Table 2) suggesting that deer density has declined throughout the forest zone. This inference was corroborated by the fact that modeled pre-harvest deer density declined between 2004 and 2005 in 37 of the 38 permit areas simulated. The total forest zone buck harvest declined $11 \%$. Results of the simulation modeling suggest that deer density declined $7 \%$ forest-wide, between 2004 and 2005 (Table 4). The decline in buck harvest was not reflected in the buck hunter success rate (buck harvest/licenses), which remained at historically high levels in 2005 in both Zones 1 and 2 (Figure 2).

Figure 2. Success of licensed hunters at killing a buck, 1994-2004.
The antlerless harvest declined in 21 of the 41 permit areas (Table 3) and the total antlerless harvest declined only 3\%. The greatest declines occurred in Permit Area 168 (48\%) and Permit Area 175 (47\%), which shifted from "managed" status in 2004 to "lottery" in 2005. Similarly, the greatest increase in antlerless harvest took place in permit area Permit Area 180 (129\%), which shifted from "lottery" in 2004 to "managed" in 2005.

The decline in the antlerless harvest was likely caused by a reduction in the number of deer in the forest. Model simulations indicated that pre-harvest density in the forest zone dropped 7\% between 2004 and 2005 (Table 4). Sales of bonus permits were roughly the same as in 2004.

The harvest by archers and muzzleloader hunters accounted for over 9\% of the total harvest in the forest zone. The archery harvest increased $18 \%$ over the previous year while the muzzleloader harvest increased by $237 \%$. Increased sales of All Season Licenses (up 28\%) likely account for these increases.

## Population Trends And Model Projections

Based on the winter severity index (WSI), the winter of 2005-06 was relatively mild throughout most of the forest zone except in the Brimson area and along the Canadian border (Figure 3). Warm temperatures in early April caused a rapid melt-off of deep snow in the "Arrowhead" and minimized the WSI.

Figure 3. Winter Severity Index (WSI) readings from winter 2004-2005. WSI readings between 100 and 180 are considered moderate.

Simulation modeling was used in 38 permit areas (Figure 1, Table 4) to approximate deer density, identify trends, and project the effect of the 2006-hunting season. To better summarize the results for this report, permit areas were lumped in to one of 5 regions (Figures 4 and 5). Deer density varied according to region with the lowest densities occurring in the Northeast (NE) and Northwest (NW). Highest densities occurred in the West Central (WC). The same basic trend occurred in all 5 areas; deer density was at the lowest level in 1997 following the severe winters of the mid-1990's and then steadily increased to peak density in 2003 in response to low (or no) antlerless permits and mild winters. Since 2003, the declines in the South (S), NW, and WC were a response to the high antlerless harvest. A reduced antlerless harvest ( $-9 \%$ ) in the Central (C) region resulted in a slight increase. There was less opportunity to kill antlerless deer in the NE and the decline there, was likely associated with winters that were more severe than elsewhere in the forest.

Figure 4. Population trends of deer in forest zone. Trend lines represent the groups of permit areas as illustrated in figure 5. Density represents pre-harvest density.

Figure 5. Groups of permit areas discussed in text and in figure 4.

After simulation modeling, wildlife managers in the forest zone came to consensus on the status of permit areas for the 2006 deer-hunting season. The availability of either sex permits has increased or remained liberal in an attempt to reach the tentative deer population goals identified by stakeholder groups this past spring. Managers recommended that only 4 permit areas be designated as "Lottery" areas with a total of 800 permits. These areas included 2 areas in the Northeast, the Fond du Lac Indian Reservation, and Mille Lacs WMA (Figure 6). Nineteen permit areas were designated as "Intensive" and the remaining 20 areas were designated as "Managed".

Figure 6. Final designation of permit areas in Minnesota's Forested Zone. The number of either-sex permits is listed within each lottery area.

Table 1. Total registered deer harvest for Deer Permit Areas in Minnesota's Forested Zone.

| Permit Area | 1996 | 1997 | 1998 | 1999 | 2000 | 2001 | 2002 | 2003 | 2004 | 2005 | Change |

# Aerial Moose Survey, 2006 

Mark S. Lenarz, Forest Wildlife Populations and Research Group

## INTRODUCTION

Each year, we conduct an aerial survey in northern Minnesota in an effort to monitor moose (Alces alces) numbers and identify fluctuations in the status of Minnesota’s largest deer species. The primary objectives of this annual survey are to estimate moose numbers and determine the calf:cow and bull:cow ratios. These data are subsequently used in a simulation model to identify population trends and the harvestable surplus.

## METHODS

We used a stratified random block survey protocol originally developed in Alaska to estimate moose population parameters (Gasaway et al. 1986). Briefly, moose numbers and age/sex ratios were estimated by flying transects within a stratified random sample of survey plots (Figure 1). As in 2005, all survey plots were rectangular ( $5 \times 2.67 \mathrm{mi}$.) and all transects were oriented east to west. The survey was conducted using helicopters (Bell Jet Ranger) flown by DNR Enforcement pilots. Moose were sexed using the presence of antlers, shape of the bell, nose color and/or vulval patch (Mitchell 1970), and calves were identified on the basis of size and behavior. UTM coordinates for all moose observed within the plots were recorded. A suite of covariates was recorded each time moose were located, including environmental variables (temperature, snow depth, wind speed), group size, cover type, and the amount of visual obstruction.

Figure 1. Northeast moose survey area and sample plots (diagonal lines) flown in the 2006 aerial moose survey.

Test plots (one-half of a rectangular plot) containing 1 or more radio-collared moose also were flown during the survey with the same protocol used on regular survey plots. If radio-collared moose known to be in the test plot were not observed from transects, they were located using telemetry following completion of the plot. Each time a radio-collared moose was located, the suite of covariates mentioned above was collected. These data were used to develop a logistic regression model or "sightability model" (Ackerman 1988, Anderson and Lindzey 1996, Otten et al. 1993, Quayle et al. 2001, Samuel et al. 1987) to correct for animals not seen during the aerial survey. This sightability model was also used to recalculate the population estimate, bull:cow and calf:cow ratios from the 2004 and 2005 surveys.

## RESULTS

The survey was initiated on 6 January and completed on 26 January. Survey conditions were rated as "Good" (highest rank) on all 37 plots, in part because snow depth was greater than 16 ". During the survey flights, 388 moose were located on the 37 plots ( $492 \mathrm{mi}^{2}$ ) and included 158 bulls, 154 cows, 60 calves, and 16 unidentified moose.

Thirty-eight radio-collared moose were located in 29 test plots; 20 were observed from transects and 18 were located using telemetry. A sightability model was developed from locations of radio-collared moose observed in 2004 and 2005. The model with the highest predictive reliability incorporated a single covariate, the amount of visual obstruction (VOC) (Giudice and Fieberg, unpubl.). The inverse of the probability of detection calculated with this model was used to "correct" the number of moose in each moose observation

Based on the moose observed on the survey plots and "corrected" by the sightability model, the estimated moose population in northeastern Minnesota numbered 7,272 $\pm 1,917$ (Table 1). Estimates of the calf:cow and bull:cow ratio were 0.33 and 1.06 , respectively (Table 1).

Table 1. Estimated moose numbers, calves:cow, bulls:cow, and percent cows with twins from aerial surveys in northeastern Minnesota.

| Survey | $\underline{\text { Estimate }}$ | Calves/ Cows | Bulls/Cows | \% Cows <br> w/ Twins |
| :--- | :---: | :---: | :---: | :---: |
| $\mathbf{1 9 9 7}$ | $3,960 \pm 35 \%$ | 0.49 | 1.57 | 1 |
| $\mathbf{1 9 9 8}$ | $3,464 \pm 36 \%$ | 0.71 | 0.98 | 0 |
| $\mathbf{1 9 9 9}$ | $3,915 \pm 35 \%$ | 0.57 | 1.30 | 9 |
| $\mathbf{2 0 0 0}$ | $3,733 \pm 25 \%$ | 0.70 | 1.34 | 7 |
| $\mathbf{2 0 0 1}$ | $3,879 \pm 28 \%$ | 0.61 | 1.05 | 5 |
| $\mathbf{2 0 0 2}$ | $5,214 \pm 23 \%$ | 0.93 | 1.22 | 20 |
| $\mathbf{2 0 0 3}$ | $4,161 \pm 37 \%$ | 0.70 | 2.01 | 11 |
| $\mathbf{2 0 0 4}$ | $9,489 \pm 35 \%$ | 0.42 | 1.19 | 4 |
| $\mathbf{2 0 0 5}$ | $6,519 \pm 30 \%$ | 0.50 | 0.91 | 9 |
| $\mathbf{2 0 0 6}$ | $7,272 \pm 26 \%$ | 0.33 | 1.06 | 5 |

## DISCUSSION

We have used the sightability model approach for 3 years to estimate moose numbers in northeastern Minnesota. In the first year, 3 observers equated VOC to crown closure on some observations and this tended to over-estimate VOC. As a result, the 2004 population estimate was biased high (Table 1). In 2005 and 2006, observations of VOC were not significantly different ( $n_{2005}=173, n_{2006}$ $=164, t=0.77, P=4393$ ) and population estimates were more comparable. Although the 2006 population estimate was $12 \%$ higher than the 2005 estimate, the overlap in confidence intervals (Table 1) implies that there was no statistical difference between these point estimates. The 2005 and 2006 estimates are likely more accurate than estimates prior to 2004.

Use of a sightability model to "correct" observations assumes that the detection probability does not differ among years. The model coefficients and odds ratios were similar between 2005 and 2006 (Giudice and Fieberg, unpubl.), which suggests a consistent detection function. "The sightability model built on the 2005-06 data should perform reasonably well in future years if the relationship between VOC and detection probability is similar over time" (Giudice and Fieberg, Unpubl.). We intend to collect additional information for the sightability model for at least two more years to test for annual variability and allow for testing of other possible models.

Given that the 2004 estimate was biased high, it should not be inferred that the 2005 and 2006 population estimates represent an increase from 2003 (Table 1). We are using a new procedure to estimate moose numbers and the estimates are not directly comparable.

Prior to 1998 we initiated the survey each year as soon as there was 8 to 12 inches of snow on the ground in the survey area. Analyses indicated, however, that estimated population size declined as a function of the starting date (Lenarz 1998). In 1993, for example, we began the survey on 4 January and the estimate was 4,421 ; in the following year, we began the survey on 9 December and the estimate increased to 6,005 . A mid-winter shift to coniferous cover, where moose are more difficult to see, is common to moose populations throughout the boreal forest (Lynch 1975, Peek et al. 1976, Crête et al 1986, Peterson and Page 1993) and likely contributes to this bias. To deal with this relationship, we changed the survey protocol in 1998 so that the survey was initiated on a consistent starting date in early January. With this change, we acknowledged that population estimates were biased low, but believed that results were more comparable among years. Estimates in 2005 and 2006 better account for differences in visibility during the survey, and corroborate the inference that population estimates between 1998 and 2003 were biased low.

The estimated bull:cow ratio (Table 1) was not significantly different from the average estimated for the previous 21 years ( $\overline{\times}=1.18, t=1.72, P=0.10$ ). The hunter harvest has been heavily biased towards bulls in recent years (Lenarz, unpubl.), but still represents less than $6 \%$ of the estimated number of bulls in the population in most years. This harvest of bulls appears to have little impact on the bull:cow ratio at the population level. It has been speculated that reproduction would decline if the bull:cow ratio declines below some unspecified level (e.g. Rausch 1974). Thompson (1991), however, found no relationship between calf:cow and bull:cow ratios. With a bull:cow ratio consistently near 1 as has been estimated for northeastern Minnesota, it is likely that there should be sufficient numbers of bulls to breed cows.

The estimated calf:cow ratio (Table 1) was significantly lower than the average estimated in the previous 21 years ( $\bar{x}=0.58, t=7.02, P<0.001$ ) and may be related to low calf production. Gross production for radio collared cows in 2004 and 2005 was only 0.82 and 0.84 calves:cow, respectively (Lenarz, unpubl.). The proportion of twins, was also lower, but not significantly different ( $\bar{x}=6.4 \%, t$ $=7.2, P=0.085$ ). Only $11 \%$ of the radio-collared moose had new born twin calves in May of 2005 (Lenarz unpubl.). Twinning rates vary widely across North America, and may be related to habitat quality and the relationship between a moose population and the carrying capacity of its habitat (Gasaway et al. 1992).

In the January survey, only $3 \%$ of the moose exhibited hair loss, which is indicative of infestation with the winter tick (Dermacentor albipictus). Moose will often rub off patches of hair when high numbers of the tick begin to engorge. Normally, hair loss associated with winter ticks doesn't become noticeable until later in the winter.

## ACKNOWLEDGMENTS

These surveys would not be possible without the excellent partnership between the Division of Enforcement, the Division of Fish and Wildlife, the Fond du Lac Band and the 1854 Authority. In particular, I would like to thank Mike Trenhom for coordinating all of the helicopters and pilots; Dan Litchfield for coordinating flights and survey crews; and Mike Schrage (Fond du Lac) and Andy Edwards (1854 Authority) for securing supplemental survey funding from their respective groups. I also want to thank Dan Litchfield, Tom Rusch, Andy Edwards, Mike Schrage, and Kevin Carlisle who flew as observers; it takes dedication and a strong stomach. I thank John Fieberg and John Giudice for their
analyses in creating and applying the sightability model. Finally, I want to thank Barry Sampson for the countless hours he has spent creating and improving the GIS survey maps

## MIGRATORY BIRD POPULATIONS

Wetland Wildlife Populations and Research<br>102 23rd Street<br>Bemidji, MN 56601<br>(218) 755-2973

# 2006 Waterfowl Breeding Population Survey Minnesota 

Steve Cordts, Wetland Wildlife and Populations Research

#### Abstract

The number of breeding waterfowl in a portion of Minnesota has been estimated each year since 1968 as a part of the overall inventory of North American breeding waterfowl. The survey consists of aerial observations supplemented by more intensive ground counts on selected routes to determine the proportion of birds counted by the aerial crew. Procedures used are similar to those used elsewhere across the waterfowl breeding grounds. The 2006 aerial survey portion was flown from 4-24 May. Pond numbers decreased $12 \%$ compared to 2005 and were 15\% below the long-term average. Estimated numbers of temporary (Type 1) wetlands increased $85 \%$ from 2005 but remained below ( $-22 \%$ ) the longterm average. The mallard breeding population $(161,000)$ declined significantly $(-33 \%, \mathrm{P}=0.04)$ from $2005(238,500)$. Mallard numbers were well below the 10 -year average ( $-51 \%$ ) and the long-term average ( $-28 \%$ ) and were the lowest recorded since 1983. The blue-winged teal breeding population $(174,000)$ was below the 2005 estimate $(194,000)$ and both the 10 -year $(-27 \%)$ and long-term $(-24 \%)$ averages. Populations of "other" ducks $(187,000)$, excluding scaup, decreased $6 \%$ and remained below the 10 -year average $(-24 \%)$ but similar to the long-term average ( $+5 \%$ ). Wood ducks ( $30 \%$ ), ring-necked ducks $(29 \%)$, and gadwalls $(19 \%)$ accounted for most $(78 \%)$ of the total population of "other" ducks. Wood duck numbers were the lowest recorded since 1985. The estimates of canvasback, redhead and scaup abundance were the lowest on record. The estimate of total ducks ( 521,000 ), which excludes scaup, decreased $18 \%$ compared to 2005 and was $36 \%$ below the 10 -year average and $17 \%$ below the long-term average ( 630,000 ). Canada goose numbers (uncorrected for visibility) decreased $9 \%$ compared to 2005 , were $8 \%$ below the 10 -year average but remained $90 \%$ above the long-term average. Survey timing in 2006, or other factors, may have contributed to lower estimates of duck abundance. Spring phenology (ice-out, leaf-out, duck migration) was well advanced in 2006, up to 10 days earlier than normal. Weather delays resulted in most (80\%) of the survey being flown after 15 May. During most years, some migrant ducks are counted during the survey. Few migrant ducks were in the state this spring during the time when most of the survey was flown.

## METHODS

The aerial survey is based on a sampling design that includes three survey strata (Table 1, Figure 1). The strata cover $39 \%$ of the state area and are defined by density of lake basins (>10 acres) exclusive of the infertile northeastern lake region. The strata include the following:

Stratum I: high density, 21 or more lake basins per township.

Stratum II: moderate density, 11 to 20 lake basins per township.

Stratum III: low density, 2 to 10 lake basins per township.

Areas with less than two basins per township are not surveyed. Strata boundaries were based upon "An Inventory of Minnesota Lakes" (Minnesota Conserv.

Figure 1. Location of waterfowl breeding population survey strata in Minnesota.

Dept. 1968:12). Standard procedures for the survey follow those outlined in "Standard Operating Procedures for Aerial Waterfowl Breeding Ground Populations and Habitat Surveys in North America" (USFWS/CWS 1987). Changes in survey methodology were described in the 1989 Minnesota Waterfowl Breeding Population

Survey report. Pond and waterfowl data for 1968-74 were calculated from Jessen (1969-72) and Maxson and Pace (1989).

All aerial transects in Strata I-III (Table 1) were flown using a Cessna 185 (N105NR). Wetlands were counted on the observer's side of the plane ( 0.125 mile wide transect) only; a correction factor obtained in 1989 was used to adjust previous data (1968-88) that was obtained when the observer counted wetlands on both sides of the plane ( 0.25 mile wide transect).

During the 2006 survey, we used the U.S. Fish and Wildlife Service computer program RECORD to capture data in the airplane (Jack Hodges, US Fish and Wildlife Service, Migratory Bird Management-Juneau, AK). We mounted 2 laptop computers in the rear of the plane and connected them to the plane GPS. Data were recorded and stored as WAV files through the plane intercom system (pilot) or a remote microphone/mouse system (observer). When the microphones were keyed, an associated GPS location was captured in a POS file so that each wetland or waterfowl observation would have an approximate GPS location associated with it. The TRANSCRIBE portion of the software, which allows users to transcribe WAV files and summarize data, was used for data entry.

Visibility correction factors (VCFs) were derived from intensive ground surveys on 14 selected routes flown by the aerial crew. Many of these routes use a county road as the mid-point of the transect boundary which aids in navigation and helps ensure the aerial and ground crews survey the same area. Ground routes each originally included approximately 100 wetland areas; however, drainage has reduced the number of wetlands on most of the routes. All observations from both ground crews and aerial crews were used to calculate the VCFs.

The SAS computer program was modified in 1992 to obtain standard errors for mallard and bluewinged teal breeding population estimates. These calculations were based upon SAS computer code written by Graham Smith, USFWS-Office of Migratory Bird Management. Estimates for 2005 and 2006 were compared using two-tailed Z-tests.

## Survey Chronology

The 2006 aerial survey began on 4 May in southern Minnesota and concluded in northern Minnesota on 24 May. The survey was completed in 13 days of flight time. Transects were flown on 4-7 and 16-24 May. Flights began no earlier than 7 AM and were completed by 12 PM each day. No flights were conducted from 8-15 May due to low ceilings, high winds ( $>20 \mathrm{mph}$ ) or precipitation events. Most (80\%) of the survey was completed after 15 May; the entire survey spanned 21 days, which was similar to both 2004 (22 days) and 2005 (27 days) but one of the longer periods on record.

## Weather And Habitat Conditions

Wetland conditions in spring 2006 were similar to 2005. Ice out on most lakes across the state occurred 10+ days earlier than average. April temperatures averaged $6.3^{\circ} \mathrm{F}$ above normal

Figure 2. Number of May ponds (Types II-V) and long-term average (dashed line) in Minnesota, 19682006.
statewide; regional temperatures ranged from $7.5^{\circ} \mathrm{F}$ above average in northwest Minnesota to $5.5^{\circ} \mathrm{F}$ above average the southwest portion of Minnesota
(http://climate.umn.edu/cawap/monsum/0604.txt). April precipitation was 1.0 inch above normal statewide and ranged from 0.38 inches below normal in the northeast to 2.3 inches above normal in the southwest. May temperatures averaged about $1.3^{\circ} \mathrm{F}$ above normal statewide. May precipitation was 0.73 inches below normal statewide and ranged from 1.76 inches below normal in southwest Minnesota to 0.36 inches above normal in northeast Minnesota
(http://climate.umn.edu/cawap/monsum/0605.txt). Additional temperature and precipitation data are provided in Appendix A.

In late April 2006, statewide topsoil moisture indices were rated as $12 \%$ very short or short, $75 \%$ adequate, and $13 \%$ surplus moisture. On June 2, statewide indices were rated as $22 \%$ short, $72 \%$ adequate and $6 \%$ surplus moisture.
(Minnesota Agricultural Statistics Service Weekly Crop Weather Reports, http://www.nass.usda.gov/mn/). For comparison, in late April 2005 statewide topsoil moisture indices were rated as $4 \%$ very short or short, $84 \%$ adequate, and $12 \%$ surplus moisture.

Planting dates for row crops were earlier in 2006 than previous years. By May $1,48 \%$ of the corn acres had been planted statewide compared to $36 \%$ in 2005 and $35 \%$ for the previous 5-year average. Dry conditions later in May allowed for a much earlier initial cutting of alfalfa hay across the state. By June 4, $56 \%$ of alfalfa hay had been cut compared to $8 \%$ in 2005 and a 5 -year average of $17 \%$ (Minnesota Agricultural Statistics Service Weekly Crop Weather Reports, http://www.nass.usda.gov/mn/).
Wetland numbers (Type II-V) decreased 12\% from 2005 and were $20 \%$ below the 10 -year average (Table 2 ) and $15 \%$ below the long-term average (Table 2; Figure 2). The numbers of temporary (Type 1) wetlands increased $85 \%$ from 2005, were $8 \%$ above the 10 -year average but remained $22 \%$ below the long-term average.

Leaf-out dates were considerably earlier than 2005, even during the early portion of the survey, which made visibility from the air extremely difficult throughout the survey period.

## Waterfowl Populations

The number of ducks, Canada geese, and coots, by stratum, are shown in Tables 3-5; total numbers are presented in Table 6. These estimates are not corrected for visibility bias.

The 2006 waterfowl breeding population estimate of mallards was 160,715 ( $\mathrm{SE}=24,230$ ), which was $33 \%$ lower and significantly different $(\mathrm{Z}=2.08, \mathrm{P}=0.04)$ than 2005

Figure 3. Mallard population estimates (adjusted for visibility bias) and long-term average (dashed line) in Minnesota, 1968-2006.

Figure 4. Blue-winged teal population estimates (adjusted for visibility bias) and long-term average (dashed line) in Minnesota, 1968-2006.

Figure 5. Other duck (excluding scaup) populations (adjusted for visibility bias) and longterm average (dashed line) in Minnesota, 19682006.
(Table 7, Figure 3). Mallard numbers were below (-51\%) the 10 -year average and the long-term average (-28\%). Mallard abundance in 2006 was the lowest recorded since 1983. In 2006, $7 \%$ of the indicated mallards were in flocks compared to $3 \%$ in both 2004 and 2005. Most of the flocked mallards consisted of groups $>5$ of male mallards, including some groups $>20$. Pairs comprised $12 \%$ of the mallards observed, compared to 29\% and $33 \%$ in 2004 and 2005, respectively.

The estimated blue-winged teal population was 173,674 (SE = 60,353), which was lower than $2005(194,000)$ but statistically unchanged from the 2005 estimate ( $\mathrm{Z}=0.39$, P $=0.77$ ). Blue-winged teal numbers were $27 \%$ below the $10-$ year average and $24 \%$ below the long-term average (Table 7, Figure 4). In 2006, $20 \%$ of the indicated blue-winged teal were in flocks compared to $29 \%$ and $25 \%$ in 2004 and 2005, respectively. Pairs comprised $57 \%$ of the blue-winged teal observed, compared to $47 \%$ and $55 \%$ in 2004 and 2005, respectively.

Other duck numbers (excluding scaup) declined 6\% to 186,719 and were $24 \%$ below the 10 -year average and $5 \%$ above the long-term average (Table 7, Figure 5). Scaup numbers $(8,300)$ were $83 \%$ lower than in 2005 and the lowest estimate on record. The total duck population, excluding scaup, was 521,000 , which was $18 \%$ lower than $2005,36 \%$ below the 10 -year average and $17 \%$ below the long-term average (Table 7, Figure 6). This was the lowest total duck estimate since 1986.

Visibility Correction Factors (VCFs) were lower in 2006 for mallards ( $-24 \%$ ) but higher for blue-winged teal $(+13 \%)$ and similar for "other" ducks ( $+4 \%$ ) compared to 2005 (Table 7). Mallard VCFs were similar ( $+4 \%$ ) to the long-term average. The blue-winged teal VCF was $17 \%$ above the longterm average. The VCF for "other" ducks was $40 \%$ above the long-term average and the $3^{\text {rd }}$ highest on record. Early leaf-out conditions decreased visibility on many transects. In addition, due to improved safety standards, the pilot and observer were required to wear flight helmets while conducting surveys this year, which decreased visibility, particularly for the observer.

Canada goose numbers (uncorrected for visibility) decreased $9 \%$ compared to 2005 and were $90 \%$ above the long-term average (Table 7, Figure 7). The VCF for Canada geese was $2.73,35 \%$ higher than 2005 and $13 \%$ above the long-term average. The population estimate of Canada geese, adjusted for visibility, increased 23\% (Table 7, Figure 8).

The estimated coot population was 15,600 , which was 65\% below the long-term average.

Figure 6. Total duck (excluding scaup) population estimate and longterm average (dashed line) in Minnesota, 1968-2006.

Figure 7. Canada goose population estimates (not adjusted for visibility bias) and long-term average in Minnesota, 1972-2006.

Figure 8. Canada goose population estimates (adjusted for visibility bias) and long-term average in Minnesota, 19882006.

## SUMMARY

Overall wetland conditions were slightly below average but similar to 2005. Numbers of Type 1 wetlands increased but numbers of Types II-V declined. Mallard abundance $(161,000)$ declined significantly from $2005(238,500)(\mathrm{P}=0.04)$ and was $51 \%$ below the 10 -year $(331,000)$ and $28 \%$ below the long-term average $(223,000)$. Blue-winged teal abundance $(174,000)$ was similar to $2005(194,000)$ ( $\mathrm{P}=0.77$ ) but $27 \%$ below the 10 -year average $(237,000)$ and $24 \%$ below the long-term average $(229,000)$. Duck abundance for most other species declined relative to 2005. Total duck abundance ( 521,000 ), excluding scaup, declined $18 \%$ from 2005 and was $36 \%$ below the 10 -year average and $17 \%$ below the long-term average. Canada goose numbers, unadjusted for visibility bias, decreased $9 \%$ from 2005 and were $8 \%$ below the 10 -year average.

## ACKNOWLEDGMENTS

Special thanks to the pilot and all the efforts of the ground crews. # Minnesota Spring Canada Goose Survey, 2006 

Stephen Maxson, Wetland Wildlife Populations and Research Group

## INTRODUCTION

This report presents results from the sixth year of a spring helicopter survey of resident Canada geese in Minnesota. The purpose of the survey is to produce a statewide population estimate with $95 \%$ Confidence Intervals.

## METHODS

The state was divided into three ecoregions (Prairie Parkland, Eastern Broadleaf Forest/Tallgrass Aspen Parklands, Laurentian Mixed Forest) hereafter referred to as Prairie, Transition, and Forest. The 7 county Metro area was excluded from the Transition ecoregion. Similarly, Lake and Cook Counties plus the Boundary Waters Canoe Area were excluded from the Forest ecoregion. Within each ecoregion, 900 $1 / 4$ section plots were randomly selected using ArcView.

The 900 plots in each ecoregion were divided into 3 strata based on habitat quality for resident geese. The 3 strata were defined as follows: 1) not nesting habitat - expect no geese, 2) limited nesting habitat - expect 1 or 2 pairs, 3 ) prime nesting habitat - expect 3 or more pairs. Stratification was based on National Wetland Inventory data and was done using ArcView. Strata were separated based on the total acres of type 3,4 , and 5 wetlands and rivers on the plot as described below:

Prairie

| No geese $=$ | ter. ( $\mathrm{=}=476$ |
| :---: | :---: |
| 1-2 pairs = | Type 3-4-5 $>0.5$ acres but Type $3<15$ acres or Type 3-4-5 $<0.5$ acres and rivers $>10$ acres. $\quad(\mathrm{n}=344$ plots). |
| $3+$ pairs $=$ | Type $3>15$ acres, but plot is not all water. ( $\mathrm{n}=80$ plots). |
|  |  |
| No geese $=$ | Type 3-4-5 $<1$ acre and rivers $<8$ acres or plot is all water. ( $\mathrm{l}=377$ plots). |
| 1-2 pairs = | Type 3-4-5 = 1-25 acres or Type 3-4-5>25 acres, but Type $3<15$ acres or Type $3-4-5<1$ acre and rivers $>8$ acres. ( $\mathrm{n}=428$ plots). |
| $3+$ pairs $=$ | Type $3-4-5>25$ acres, but Type $3>15$ acres and plot is not all water. ( $n=95$ plots). |

## Forest

No geese =
Type 3-4-5 $<2$ acres and rivers $<2$ acres or plot all water. ( $\mathrm{n}=510$ plots).
$1-2$ pairs =
$3+$ pairs $=$ Type 3-4-5 $>2$ acres, but not all water or Type 3-4-5 $<2$ acres and rivers $>2$ acres. ( $\mathrm{n}=390$ plots). None.

Plots in the No geese strata are not flown. Each year 30 plots are randomly selected in each of the 5 remaining strata and these 150 plots are surveyed at low level using a helicopter. Ideally, the survey should be conducted during mid-incubation.

Pilot John Heineman and I flew the survey 24-27 April, 2-3 May and 5 May 2006. Canada geese seen within plot boundaries were recorded as singles, pairs, and groups. We also recorded whether singles and pairs were observed with a nest. The number of singles was doubled when the total number of geese per plot was calculated (unless 2 singles were observed to associate as a pair after being flushed).

## RESULTS AND DISCUSSION

The total population estimate in the surveyed area was $358,071( \pm 108,436)$. Adding 17,500 for the Twin Cities metro area (Cooper 2004) yields a statewide estimate of 375,571 (Table 1). Confidence Intervals were $30.3 \%$ of the estimate which is somewhat above the target of $25.0 \%$. The survey tallied $43.5 \%$ singles (after doubling, as noted above), $45.9 \%$ pairs, and $10.6 \%$ groups (Table 2). Typically, many of the pairs seen on this survey are not associated with nests and are likely nonbreeders. An index to nesting effort (i.e., "Productive Geese") can be obtained by combining singles (after doubling) and pairs associated with nests. In 2006, $50.3 \%$ of the geese seen were classified as Productive Geese (Table 2). While confidence intervals overlap among years, a linear trend line applied to these data suggests the population in the surveyed area has been increasing over the 6 years of this survey (Figure 1 ).

Type 1 wetlands were few and scattered during the survey. However, water levels in Type 3, 4 and 5 wetlands appeared to be about normal. Based on habitat conditions and the relatively high proportion of productive geese observed, I would expect average to above-average Canada goose production in 2006.

## ACKNOWLEDGEMENTS

Frank Martin (Univ. of MN) was instrumental in designing the survey. Tim Loesch, Christopher Pouliot, and Shelly Buitenwerf set up the original 2,700 $1 / 4$ section plots using ArcView and were very helpful in getting the survey up and running in 2001. Shelly Buitenwerf provided GPS coordinates of plots to the pilot, and printed out maps of the 150 plots flown this year. John Giudice wrote the SAS program that analyzes the survey data.

# 2005 SMALL GAME HUNTER MAIL SURVEY 

Margaret Dexter, Wildlife Policy and Research Unit

## INTRODUCTION

The Minnesota Department of Natural Resources, Wildlife Policy and Research unit annually conducts a survey of small game hunters. Annual harvest estimates from survey data provide guidance for future hunting regulations and season structure.

## METHODS

The Wildlife Policy and Research unit requests a random sample be drawn from the Electronic License System database in late February, to ensure that each license holder has an equal chance of being in the survey sample. The sample consisted of 6,280 (approximately 2\%) Small Game License holders, drawn proportionately from each of the Small Game license types available.

Hunters that returned the survey questionnaire within three weeks, were marked returned and eliminated from follow-up mailings. Follow-up mailings were sent to non-respondents at three week intervals. There were three follow-up mailings to non-respondents.

Completed and returned questionnaires were checked for completeness, consistency, and biological practicability. Cards were marked with numeric county codes corresponding to the hunter's written information. Data from each usable card was converted to an electronic database. Data were checked for errors, duplicate responses, and /or missing data. The following is a list of assumptions made in data coding:

1) If an individual checked the box indicating (s)he did not hunt, but harvest information was provided, it is assumed that the individual did hunt.
2) If a range is given for "number of days hunted" or "number of animals harvested", the median of the range, rounded to the nearest even integer is recorded.
3) If a hunter indicates spending time hunting for a species, but leaves "number bagged" blank, the \# bagged is entered as missing data.
4) If a small game hunter indicated bagging a species, but leaves "number of days hunted" blank, then "number of days hunted" is recorded as missing data.
5) If more than one county is indicated for "county hunted in most", the first county listed is recorded. However, if the several counties listed are indicated to apply to all species hunted, then counties are recorded in sequential order in relation to species hunted.
6) If "county hunted in most" is left unanswered or not legible, the county is recorded as missing data.

Data from all usable cards are tabulated and statistically analyzed by the St. Paul staff, using SAS statistical analysis software programs.

## RESULTS

Attached are the survey results. All estimates are Statewide unless otherwise indicated.

Table 1. Small game hunter response to mail surveys, 1979-80 through 2005-06.

| Year | Number mailed | Number not delivered | Delivered questionnaires completed and returned |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Number | Percent |
| 1979-80 | 5,696 | 443 | 4,504 | 85.7 |
| 1980-81 | 6,434 | 385 | 4,963 | 82.0 |

|  |  | 3,935 (100.0\%) | 280,156 |

Includes resident and non-resident information. Excludes duplicates.

## 2005 Small Game Hunter Report

1. Did you hunt small game, listed below, in Minnesota this year (March 2005 - Feb 2006)? $\square$ No $\square$ Yes (Please check box)
2. Indicate the total number of days spent hunting small game of all species listed below, in Minnesota
3. For the species you hunted indicate your harvest, number of days hunted, and county in which you hunted most for each species, even if None were bagged. Report only game you personally bagged and retrieved in Minnesota. Do not include birds taken on shooting preserves or game farms.

## Dear Small Game Hunter:

You have been selected at random from among Minnesota's small game hunting license buyers to assist us in evaluating the 2005-2006 small game hunting season (March 2005-February 2006). We need information to estimate the season's harvest and to help set future small game seasons. Answer only for your Minnesota 2005 hunting experience.

## YOUR RESPONSE IS NEEDED

EVEN IF YOU DID NOT HUNT OR HARVEST SMALL GAME
Please fill out the attached questionnaire and mail as soon as possible A reminder will be sent to individuals not returning the questionnaire within three weeks. No envelope or stamp is necessary; just tear along the perforation and drop into a mailbox.

THANK YOU FOR YOUR COOPERATION

Harvest estimates in this table, and the number of hunters and mean take per hunter in Table 32, are calculated from different questions on the survey form. The sample used in calculations differs from one estimator to the next. This is because some respondents give specific answers to one question but not to a related one. A formula is used to calculate the tota estimated take for each species which appears in this table. In most years the formula produces results rather close to those obtained by multiplying the average take per hunter times the number of hunters. However, in other years (e.g., 1985) results of the two methods are quite divergent, perhaps as a result of an unusual sample. This is being investigated further, and as a result, numbers may change somewhat in future reports. The most current report of survey findings will have the best data available at that time. Beginning in $1989-90$ this table was
changed from Resident harvest estimates to Statewide harvest estimates, which includes non-resident harvest estimates
${ }^{a}$ Duplicate licenses not included.
${ }^{\text {b }}$ Estimates based upon response of hunters to questionnaires.
${ }^{\text {c }}$ U.S. Fish and Wildlife Service HIP harvest estimates for 2003 are:
Ducks . . . . . . . . . . . 884,500 Canada geese . . . . . . . 282,495

Raccoon and red fox seasons changed to year round beginning May,1994.
${ }^{\mathrm{e}}$ Federal duck stamps sold have not been audited for non-hunting stamp purchasers. ${ }^{\text {f. }}$ Mourning dove season added 2004.

# Hunter Activity and Goose Harvest During the September 2004 Canada Goose Hunt in Minnesota 

Stephen J. Maxson, Wetland Wildlife Populations \& Research<br>Margaret H. Dexter, Wildlife Surveys \& Statistical Unit

## INTRODUCTION

This report documents results of the 2004 September goose hunter mail questionnaire survey. The objectives of the survey are to determine the number of hunters participating in the September hunt, their hunting effort and success, the number of geese harvested by goose zone, and the proportion of geese taken while hunting within 100 yards of water in the West and Remainder of State Zones.

## METHODS

The Canada goose season in the four zones encompassing the majority of Minnesota was 4-22 September 2004 (19 days). A 12-day (4-15 Sep) season was held in the Northwest Goose Zone (Fig. 1). The daily bag limit was 5 geese per day, except in the Northwest and Southeast Goose Zones where the daily bag was two. Shooting hours were $1 / 2$ hour before sunrise to sunset. Taking of Canada geese was prohibited on or within 100 yards of all surface waters in the Northwest, Southeast, and Twin Cities Metro Goose Zones, in the Carlos Avery Wildlife Management Area and in the Swan Lake Area. In the Twin Cities Metro Zone and goose refuges open to goose hunting, hunting was not allowed from public road rights-of-way. Goose hunters were required to obtain a $\$ 4.00$ permit to participate in the September season.

Permittees were randomly selected to receive a post-season hunter survey. Questionnaires were sent to 3,100 permittees following the season. Questionnaires were individually numbered, and up to 3 questionnaires were mailed to individuals who had not responded. Completed questionnaires were double key-punched to reduce errors.

The questionnaire asked hunters which zone they hunted, number of days they hunted, number of geese taken, and number of geese knocked down and not retrieved for the season as a whole. The questionnaire also asked whether hunters in the West or Remainder of State Zones had hunted over water or within 100 yards of water and if so, how many geese they had taken.

Statistical Analysis Systems (SAS Institute Inc. 1999-2001, Version 8.2) computer programs were written to summarize responses to the questionnaire survey.

## RESULTS AND DISCUSSION

The DNR License Bureau reported that 42,235 Special Canada Goose Season permits were sold prior to 22 September, 2004. Response rate to the survey was $72.4 \%$ and $70.2 \%$ of the respondents indicated that they hunted during the September season. The majority of the hunters indicated they hunted in the Remainder Zone, followed by the West, Twin Cities Metro, Northwest, and Southeast goose zones (Table 1). The Remainder and West zones are the largest zones. Active hunters were afield an average of 3.0 to 3.9 days, and retrieved 1.5 to 3.3 geese, when totaled according to their hunt zone. Success was lowest for hunters hunting in the Southeast Zone (43.2\%) and highest in the Northwest Zone (74.3\%) (Table 1).

A total of 89,936 Canada geese was harvested with approximately $59 \%$ of the harvest in the Remainder Zone and $21 \%$ in the West Zone (Table 1). This pattern has remained rather consistent during the 2000-2004 September seasons (Table 2). The U.S. Fish and Wildlife Service adjusts their mail survey statistics by a memory and prestige response bias factor of 0.848 for geese bagged in the Mississippi Flyway (Voezler et al. 1982:56). Multiplying September Canada goose harvest by the adjustment factor would indicate a 2004 harvest of 76,266 .

Of those hunters who indicated that they hunted in the West or Remainder of State Zones (23,764 hunters, Table 1), $39.6 \%$ reported that they hunted over water or within 100 yards of water. Of the 73,323 geese harvested in these two Zones (Table 1), $28.97 \%$ were taken over water or within 100 yards of water. This was similar to the proportion of geese taken over water in the West Zone during the 20002002 September seasons (Table 3) and in the West and Remainder Zones in 2003 (Table 4).

# Hunter Activity and Goose Harvest During the September 2005 Canada Goose Hunt in Minnesota 

Stephen J. Maxson, Wetland Wildlife Populations \& Research<br>Margaret H. Dexter, Wildlife Surveys \& Statistical Unit

This report documents results of the 2005 September goose hunter mail questionnaire survey.

## METHODS

The Canada goose season in the four zones encompassing the majority of Minnesota was 3-22 September 2005 ( 20 days). A 13-day ( $3-15 \mathrm{Sep}$ ) season was held in the Northwest Goose Zone (Fig. 1). The daily bag limit was 5 geese per day, except in the Southeast Goose Zone where the daily bag was two. Shooting hours were $1 / 2$ hour before sunrise to sunset. Taking of Canada geese was prohibited on or within 100 yards of all surface waters in the Northwest, Southeast, and Twin Cities Metro Goose Zones, in the Carlos Avery Wildlife Management Area and in the Swan Lake Area. In the Twin Cities Metro Zone and goose refuges open to goose hunting, hunting was not allowed from public road rights-of-way. Goose hunters were required to obtain a $\$ 4.00$ permit to participate in the September season.

Permittees were randomly selected to receive a post-season hunter survey. Questionnaires were sent to 3,094 permittees following the season. Questionnaires were individually numbered, and up to 3 questionnaires were mailed to individuals who had not responded. Completed questionnaires were double key-punched to reduce errors.

The questionnaire asked hunters which zone they hunted, number of days they hunted, number of geese taken, and number of geese knocked down and not retrieved for the season as a whole. The questionnaire also asked whether hunters in the West or Remainder of State Zones had hunted over water or within 100 yards of water and if so, how many geese they had taken. In addition, two new questions, described in Results, were asked this year.

Statistical Analysis Systems (SAS Institute Inc. 1999-2001, Version 8.2) computer programs were written to summarize responses to the questionnaire survey.

## RESULTS AND DISCUSSION

The DNR License Bureau reported that 38,051 (down from 42,235 in 2004) Special Canada Goose Season permits were sold prior to 23 September 2005. Response rate to the survey was $66.9 \%$ and $73.2 \%$ of the respondents indicated that they hunted during the September season. Following the usual pattern, the majority of the hunters indicated they hunted in the Remainder Zone, followed by the West, Twin Cities Metro, Northwest, and Southeast goose zones (Table 1). The Remainder and West zones are the largest zones (Fig. 1). Active hunters were afield an average of 3.3 to 4.0 days, and retrieved 2.7 to 3.6 geese, when totaled according to their hunt zone. Overall, the success rate for active hunters was $68.6 \%$. The success rate and the number of geese harvested per active hunter (Table 1) was up slightly in all zones compared to 2004.

The survey estimates that 94,266 Canada geese were harvested with approximately $65 \%$ of the harvest in the Remainder Zone and $16 \%$ in the West Zone (Table 1). This harvest pattern has remained rather consistent during the 2000-2005 September seasons (Table 2). The U.S. Fish and Wildlife Service adjusts their mail survey statistics by a memory and prestige response bias factor of 0.848 for geese bagged in the Mississippi Flyway (Voelzer et al. 1982:56). Multiplying September Canada goose harvest by the adjustment factor would indicate a 2005 harvest of 79,938 .

Of those hunters who indicated that they hunted in the West or Remainder of State Zones (22,579 hunters, Table 1), $32.8 \%$ reported that they hunted over water or within 100 yards of water. Of the 76,522 geese harvested in these two Zones (Table 1), $22.3 \%$ were taken over water or within 100 yards of water.

The pattern during 2000-2005 suggests that both the proportion of hunters hunting over water and the proportion of geese harvested over water are declining (Tables 3 and 4).

Two new questions were asked on the survey this year:

1. "Would you favor a reduced bag limit (for example, from 5 to 3) during the September Canada goose season in exchange for an increase in bag limit (for example, from 1 to 2 or 2 to 3 ) during the regular Canada goose season (October-November)?" The response of 1,479 people was Yes $=49.7 \%$, No $=36.8 \%$, and Don't Know $=13.5 \%$ suggesting moderate support for this idea.
2. "Closing goose hunting at noon is used in some areas to allow geese to feed undisturbed in the afternoon and is intended to increase goose harvest. Would you favor a noon closure during the September Canada goose season?" The response of 1,482 people was Yes $=29.9 \%$, No $=58.1 \%$, and Don't know $=12.0 \%$ suggesting fairly strong opposition to this idea.

# 2006 Light Goose Conservation Order Harvest In Minnesota 

Stephen Maxson, Wetland Wildlife Populations \& Research Group<br>Margaret Dexter, Wildlife Surveys \& Statistical Unit

## INTRODUCTION

This report documents results of the 2006 Light Goose Conservation Order hunter mail questionnaire survey.

## METHODS

Minnesota held a light goose Conservation Order harvest from 1 March - 30 April, 2006. Participants were required to obtain a $\$ 3.50$ permit. No other license, stamp, or permit was required. Shooting hours were $1 / 2$ hour before sunrise to $1 / 2$ hour after sunset. There were no daily or possession limits. Use of electronic calls and unplugged shotguns were allowed.

All permit holders were sent a questionnaire after the season. Survey questions are listed in Figure 1. Second and third mailings were sent to non-respondents after one month had elapsed.

## RESULTS AND DISCUSSION

A total of 1,363 permits was issued and 955 responses ( $70.1 \%$ ) to the questionnaire were obtained (Table 1). In calculating harvest estimates, we assumed that the 408 non-respondents participated in the conservation action and took light geese in the same manner as respondents (i.e., tallies were expanded by 1.43). Relatively few light geese were present in Minnesota again this year and harvest was again concentrated in the southwest portion of the state with some also being taken in west-central Minnesota. 516 people attempted to take light geese during the 61-day conservation order period. Active participants pursued light geese for 2,665 days and 1,360 light geese were shot and retrieved. This was an average retrieved take of 2.6 geese per active participant. Another 163 light geese were reported wounded and not retrieved.

Unplugged shotguns were used by 215 (41.7\%) individuals to take 689 (50.1\%) geese. 287 $(41.7 \%)$ of these were taken with the $4^{\text {th }}, 5^{\text {th }}$, or $6^{\text {th }}$ shell. Electronic calls were used by 73 (14.1\%) participants to take 280 ( $20.6 \%$ ) light geese. 223 (43.2\%) of the active participants hunted during the $1 / 2$ hour after sunset period to take 246 (18.1\%) geese.

Figure 1. Questionnaire mailed to Light Goose Conservation Order license holders.

## MINNESOTA 2006 LIGHT GOOSE HARVEST SURVEY <br> For the Period of March 1 - April 30, 2006 ONLY

You are being asked to provide information to help us evaluate the harvest of light geese (snow, blue, and Ross' geese) in Minnesota during March 1 - April 30, 2006. Your cooperation is important. Please return this survey card even if you did not hunt light geese. Please answer the following questions to the best of your ability.
Please answer only for your Minnesota 2006 hunting experience.
THANK YOU! Dave Schad, Director, Division of Fish and Wildlife, MN DNR.

1. Did you hunt light geese in Minnesota during March 1 - April 30, 2006? Yes / No

If NO, please disregard all remaining questions and return this survey card.
2. How many days did you hunt light geese in Minnesota during March 1 - April 30, 2006 ? $\qquad$
3. In what county did you hunt light geese most often during March 1 - April 30, 2006?
4. How many light geese did you personally shoot and retrieve in Minnesota?
5. How many light geese did you personally shoot, but were UNABLE to retrieve?
6. Did you hunt light geese in Minnesota with a gun(s) that was holding more than 3 shells? Yes / No
7. If yes, how many light geese did you shoot with a gun holding more than 3 shells? $\qquad$
8. How many light geese did you shoot and retrieve with the $4^{\text {th }}, 5^{\text {th }}$, or $6^{\text {th }}$ shell? $\qquad$
9. Did you hunt light geese in Minnesota with the aid of an electronic caller? Yes / No
10. If yes, how many light geese did you shoot and retrieve with the aid of an electronic caller? $\qquad$
11. Did you hunt light geese in Minnesota during the $1 / 2$ hour after sunset period? Yes / No
12. If yes, how many light geese did you shoot and retrieve during the $1 / 2$ hour after sunset period? $\qquad$

## Dear Light Goose Permit holder:

You are being asked to assist us in evaluating the March 1 - April 30, 2006 Light Goose Conservation Order. Please answer only for your Minnesota 2006 hunting experience.

## YOUR RESPONSE IS NEEDED EVEN IF YOU DID NOT HUNT THIS YEAR.

Please fill out the attached questionnaire and mail as soon as possible. A reminder will be sent to individuals not returning the questionnaire within three weeks. No envelope or stamp is necessary; just tear along the perforation and drop into a mailbox.

THANK YOU FOR YOUR COOPERATION
Dave Schad, Director
Division of Fish and Wildlife
Department of Natural Resources

# 2005 Fall Wild Turkey Harvest Report 

Sharon Goetz and Allison Boies, Farmland Wildlife Populations and Research Group

## INTRODUCTION

In Minnesota, monitoring wild turkey harvest is an important component of population
 management, which includes setting permit levels for subsequent seasons. Wild turkey populations, permit levels available for the fall season, and harvest have all increased since Minnesota's first fall hunting season in 1990. Fall harvest is affected by wild turkey population size, by harvest pressure, and weather conditions during the fall hunting season.

## METHODS

The 2005 fall turkey season took place from 12 October through 23 October (2, 5-day periods). There were 4,410 permits available in the 24 permit areas open to fall hunting, with a total of 4,542 applicants (Table 1). Available permits increased by 30 permits from 2004 (4,380). Spring turkey hunters are required to register their bird at a designated registration station within 24 hours of harvest. During registration sex, age, and harvest date are recorded.

## RESULTS AND DISCUSSION

This year's harvest of 681 was down from 2004 (758), and from the 5-year average of 721 (Table 1). The highest harvest occurred in permit area 341 with a total of 88 turkeys registered (Table 2, Figure 1). Hunter success rate was $25 \%$ overall, which is below the long-term average of $32 \%$. Half of the harvest occurred during Season A (October 12-16), and half during Season B (October 19-23). Hunter numbers were down 299 this year, but were still greater than the 5-year average of 2,789 fall turkey hunters. Hunter effort is one factor that impacts fall turkey harvest, and could have contributed to lower harvest levels in 2005.

Females comprised 65\% of the overall reported harvest, with adult females accounting for $45 \%$ of the harvest alone (Table 3 and 4). Juveniles made up $35 \%$ of the harvest (Table 4), this is higher than 2004 (23\%). Harvest age ratios are biased by hunter preference for taking adult turkeys. Also, because age data are hunter reported, some juvenile birds are likely misclassified as adults (i.e., it is assumed that hunters are more likely to report shooting an adult).

Figure 1. Total harvest, permits issued, and hunter success rate for the 2005 fall wild turkey hunting season in Minnesota.

# 2006 Spring Turkey Harvest Report 

Sharon Goetz, Farmland Wildlife Populations and Research Group<br>Allison Boies, Minnesota State University - Mankato

## INTRODUCTION

In Minnesota, monitoring wild turkey harvest is an important component of population management, which includes setting permit levels for subsequent seasons. Wild turkey populations, permit levels available for the spring season, and harvest have all increased substantially since Minnesota’s first modern hunting season in 1978. Spring harvest is affected by wild turkey population size, by harvest pressure, and weather conditions during the spring hunting season.

## METHODS

Spring turkey hunting opportunities are now available in approximately half of Minnesota (Figure 1). The 2006 spring turkey season took place from 12 April through 25 May ( 65 -day time periods and 2 7 -day time periods). An archery permit was offered the last 2 time periods in any permit area with at least 50 permits per time period. Spring turkey hunters are required to register their bird at a designated registration station within 24 hours of harvest. During registration sex, age, and harvest date are recorded.

## RESULTS

A total of 45,704 applications were received for the 32,624 available permits (Table 1). The chance of being drawn for a permit varies by permit area (PA) and time period selected by the hunter (Table 2). There were 27,876 total regular permits and 2,801 archery permits issued. Surplus permits that were sold after the initial lottery drawing accounted for $7 \%(1,908)$ of regular permit sales (Figure 2).

A total of 8,241 turkeys were registered in spring 2006 compared to 7,800 in 2005 (Table 1, Figure 3). Overall hunter success was $29.6 \%$, slightly higher than last year (28.2\%) and slightly lower than the 5 -year average of $31.1 \%$. The highest harvest occurred in PA 349 where 552 turkeys were registered (Table 3). Most PAs (64\%) showed increased ( $n=38$ ) or identical ( $n=4$ ) harvests from 2005. Hunter success by PA ranged from 9.1\% (recently split PA 456) to 60.4\% (PA 221; Table 3). Hunters in the first 2 time periods had the highest success rates ( $39.3 \%$ and $39.1 \%$, respectively), with lower success rates in subsequent time periods, following the 5 -year trend (Table 4, Figure 4).

Juveniles made up $29 \%$ of the harvest (Table 5, Figure 5), which is higher than the past 3 years ( $10 \%$ in $2005,20 \%$ in 2004, and $23 \%$ in 2003). Wisconsin reported similar juvenile harvest of $28 \%$ for spring 2006 ( $12 \%$ in 2005 , $22 \%$ in 2004, and $24 \%$ in 2003). Harvest age ratios are biased by hunter preference for taking adult gobblers. Also, because age data are hunter reported, some juvenile birds are likely misclassified as adults (i.e., it is assumed that hunters are more likely to report shooting an adult).

Total huntable area (forest cover buffered by 50 meters, with non-huntable areas removed) is used to calculate harvest density (Table 6). The number of turkeys harvested per square mile of huntable habitat ranged from 0.05 (PA 456) to 4.61 (PA 343) with an average of 0.99 statewide (Table 6).

No new turkey hunting accidents were reported during spring 2006. Thirteen spring hunting accidents have been reported since 1978, none of which has been fatal.

## DISCUSSION

Total harvest for spring $2006(8,241)$ was slightly up from spring $2005(7,800)$. The increase occurred mostly from harvest in time period $G$, with about twice as many birds harvested in 2006. Time period G was cold and rainy in 2005 that likely led to decreased hunter effort and possibly gobbler activity as well. Weather conditions for spring hunting in 2006 were good, with one rainy spell over the weekend in the $4^{\text {th }}$ time period (D), and some cooler weather during portions of time periods F and G .

# 2005 Minnesota Prairie-Chicken Hunter Survey Report 

Michael A. Larson, Forest Wildlife Populations and Research Group

## INTRODUCTION

Hunting seasons for prairie-chickens (Tympanuchus cupido pinnatus) in Minnesota were closed from 1943 through 2002. During October 2003 a limited-entry, 5-day hunting season for prairie-chickens was held within 7 contiguous permit areas in western Minnesota (Figure 1). Permits were awarded through a lottery system, and each hunter could harvest a maximum of 2 prairie-chickens. The same format was implemented for prairie-chicken hunting seasons during 23-27 October 2004 and 22-26 October 2005.

The prairie-chicken permit areas are located in a portion of Minnesota that is closed to the hunting of sharp-tailed grouse (T. phasianellus campestris). A new rule effective during the 2005 hunting season allowed permitted prairie-chicken hunters who were also properly licensed for taking sharp-tailed grouse to take sharp-tailed grouse while hunting prairie-chickens. The new rule eliminated the need for prairie-chicken hunters to distinguish between the 2 species, which are similar in appearance.

## METHODS

Results of the 2005 hunting season came from 2 sources. First, the Electronic Licensing System (ELS) recorded all permit applications, lottery results, and the mandatory registration of each prairiechicken that was harvested. Second, I sent a post-season survey by mail to all hunters who purchased a prairie-chicken permit. The survey consisted of 14 questions. Twelve of the questions were identical to those in surveys sent to prairie-chicken hunters during 2003 and 2004. The other 2 questions were new and were related to the harvest of sharp-tailed grouse during the prairie-chicken hunt.

## RESULTS AND DISCUSSION

One hundred ten prairie-chicken hunting permits were available during 2005; 100 were available during 2003 and 2004. Ninety-two (19\%) of 487 regular applicants were awarded permits (Table 1). The number of regular applicants declined from 835 in 2003 and 734 in 2004. During 2005 an additional 12 permits were awarded through a separate lottery to hunters who applied as landowners or tenants of $\geq 40$ acres of grassland within a permit area ( $92 \%$ success). There were 18 and 25 landowner applicants during 2003 and 2004, respectively.

Harvest results from the ELS and hunter survey differ for several reasons. First, not all hunters returned a survey. Eighty-two hunters responded to the first mailing of the survey, and 3 responded to the second mailing, so the response rate was $92.4 \%$. Second, $6(7.1 \%$ of $)$ hunters who purchased a permit and responded to the survey reported that they did not hunt. Third, hunters who registered prairiechickens in ELS may not have been the same hunters who reported killing them.

The number of prairie-chicken hunters, amount of time spent hunting, hunting methods, and number of prairie-chickens flushed have been similar during the last 3 years (Figures 2-5). Hunters killed and retrieved approximately 89,55 , and 129 prairie-chickens during 2005, 2004, and 2003, respectively (Table 2). Six percent of hunters $(n=79)$ reported knocking down a prairie-chicken and not being able to retrieve it during 2005. Approximately $60 \%$ of hunters harvested at least 1 prairie-chicken during 2005, which was similar to the success rate during 2003 (68\%) but not 2004 ( $46 \%$ ). Only 18\% of prairiechicken hunters $(n=78)$ reported also flushing sharp-tailed grouse, but 7 of them flushed $10-25$ sharptailed grouse each. No hunters reported wounding or retrieving a sharp-tailed grouse while hunting prairie-chickens.

Thirty-two percent of prairie-chicken hunters ( $n=79$ ) hunted only on public land, $25 \%$ hunted only on private land, and $43 \%$ hunted on both public and private land during 2005. The percentages were nearly identical during 2004. Of the 45 hunters who reported their ease of gaining access to private land
and who had not applied for a permit as a landowner or tenant, $47 \%, 49 \%, 4 \%$, and $0 \%$ reported it being very easy, somewhat easy, somewhat difficult, and very difficult, respectively. This distribution was only slightly different than when landowners themselves were added to the sample (Figure 6).

Hunter satisfaction with the 2005 prairie-chicken hunting season was reported as a median of 8.0 (mean =7.7) on a $1-10$ scale ( $n=79$, Figure 7), and $88 \%$ of hunters $(n=77$ ) reported that they would apply for a prairie-chicken permit again in the future. Twelve prairie-chicken hunters ( $15.6 \%, n=77$ ) reported being interfered with by other hunters a total of 16 times during 2004.

## ACKNOWLEDGMENTS

Wendy Krueger, Richard Kimmel, and others developed and initially implemented the hunter survey for the 2003 prairie-chicken hunt. Wendy also provided the map in Figure 1. I thank all the hunters who responded to the survey for their cooperation and Mark Lenarz for reviewing a draft of the report.

Lou Cornicelli, Big Game / Season Program Consultant, Division of Fish and Wildlife

## INTRODUCTION

The white-tailed deer may be considered Minnesota's most popular wildlife species. Each year 500,000 hunters harvest over 200,000. In 2005, hunters registered 255, 736 deer. This harvest marked the third highest harvest recorded in Minnesota.

## METHODS

Every deer taken by hunting in Minnesota must be registered within 24 hours of the close of the season under which the deer was taken. Deer may be registered at any of the 825 "Big Game Registration" stations available throughout the state. Implementation of electronic licensing (ELS) has improved the efficiency and accuracy of deer harvest estimates and provides a more timely release of harvest information. Registered deer are recorded as adult buck, fawn buck, adult doe, or fawn doe. Additional information gathered at time of registration includes date of kill, deer permit area, and season.

## RESULTS

Outcome of the 2005 deer harvest are presented in the following tables.

Table 1. Statewide Firearms, Archery, and Muzzleloader Harvest, License Sales, and Success Rates 1994-2004.

| REGULAR FIREARMS |  |  |  |  |  |  |  |  |  |  |  |

| 2 | 107,754 | 25,443 | 36,623 | 62,066 | $57.6 \%$ |
| 3A | 18,454 | 5,440 | 2,424 | 7,864 | $42.6 \%$ |
| 3B | 20,685 | 2,840 | 8,252 | 11,092 | $53.6 \%$ |
| 4A | 66,578 | 14,255 | 15,316 | 29,571 | $44.4 \%$ |
| 4B | 30,193 | 7,204 | 10,781 | 17,985 | $59.6 \%$ |
| Multi-Zone Buck $_{\text {Free Landowner }}{ }^{1}$ | 28,233 | 5,830 | 0 | 5,830 | $20.6 \%$ |
| All-Season Deer $^{1}$ | 59,196 | 0 | 1,314 | 1,314 | $31.3 \%$ |
| Muzzleloader | 32,519 | 14,957 | 18,099 | 33,056 | $55.9 \%$ |
| Archery | 3,613 | 11,808 | 15,421 | $47.4 \%$ |  |
| TOTAL ${ }^{\text {³ }}$ | 75,989 | 7,236 | 16,302 | 23,538 | $24.6 \%$ |

Includes deer taken during regular firearms, muzzleloader, and archery seasons Includes Camp Ripley and all-season harvest. Total number of people who bought only an archery license was 23,737 .
Due to the fact that a hunter can buy multiple licenses, hunter numbers are an estimate.
${ }^{4}$ Column totals do not add to 255,736 because all-season firearm harvest was placed in appropriate zone.

Figure 2. 2005 Deer Permit Areas.

# 2005 Minnesota Bear Harvest Report 

David Garshelis, Karen Noyce, Pam Coy, Forest Wildlife Populations and Research Group

## INTRODUCTION

Out of concern that the Minnesota bear population was being overharvested, a quota on hunting licenses was instituted within the primary range in 1982. Eleven bear management units (BMUs) have been designated (Figure 1), with separate quotas for each. Outside the primary bear range, where bear depredation to crops is a primary concern, license sales are unlimited (no-quota area), and hunters can purchase licenses before or during the bear season. In recent years, hunters in this area could harvest 2 bears, and beginning in 2005 hunters could purchase both a quota and no-quota license (although only 3 people shot bears in both areas). In all areas the bear season runs from September 1 through mid-October.

Corresponding with the change in bear management in 1982, a long-term telemetry study was initiated near the center of the bear range to monitor reproductive rates and to design methods for monitoring population size and structure. All population monitoring and harvest analyses are conducted by the Wildlife Research unit in Grand Rapids. This report summarizes status and trends in harvests and population size and structure.

## METHODS

Successful hunters must register their bears at designated registration stations. Harvest data are a simple tally of these registrations, partially corrected for non-compliance (and in 2005 corrected for some lost registration data). Hunters also were required to submit a tooth from harvested bears (compliance $\approx$ $70 \%$ ) from which an age estimate was obtained. In some years hunters were also required to submit rib samples. Bear population estimates were obtained from a statewide mark-recapture using tetracycline as a biomarker and tooth and rib samples submitted by hunters as the recapture sample. Bear food abundance, which impacts hunting success, was measured qualitatively by DNR and other field personnel. Reproductive rates were obtained by visits to dens of radiocollared female bears after the birth of cubs.

## RESULTS

The number of hunting permits that were made available steadily increased through the 1980s and 1990s (Table 1) in response to increasing bear numbers. Permit availability was capped at just over 20,000 from 1999-2003, whereas during this period permit applications declined. Concomitantly, since 2001, a diminishing proportion of permittees bought licenses, resulting in 7 of 11 BMUs being undersubscribed by 2003. Permits were reduced in 2004 and again in 2005 (Table 2) in accordance with the diminishing level of interest and hunter complaints of overcrowding in some BMUs, but 6 BMUs remained undersubscribed (Table 3). Harvests, while variable due to natural food abundance, showed no trend over the past 10 years, averaging about 3400 bears, with hunting success averaging $26 \%$. Harvests during the past 3 years have been similar (3340-3600), and hunting success has been steady at $26 \%$ (Table 1). Harvest sex ratios, uncorrected for misreporting (Table 1, footnote e) averages $57 \%$ male, but varies by BMU (Table 4). In 2005, harvests (Table 4) and hunting success (Table 5) were about average for most BMUs, except the western no-quota area (designated BMU 11, Figure 1), which had a record harvest. Generally about $70 \%$ of the harvest occurs during the first week of the season (Table 6).

The number of bears killed by hunters each year is largely explained by 2 factors: fall food abundance and hunter numbers (Figure 2). Bear numbers, which increased dramatically until about 1997 but have since stabilized at 20-30,000 (Figure 3), are no longer an important factor in year-to-year variations in harvest. Nevertheless, trends in harvest age structure, specifically an increasing proportion of yearlings in the harvest (Figure 4), suggest ongoing changes in the living age structure. Likewise, reproductive rates appear to have become more variable and synchronous over the past decade (Figure 5).

## DISCUSSION

The apparent decline in interest in bear hunting is somewhat enigmatic. Interest in hunting bears seems to have waned as permit availability peaked, corresponding with complaints by hunters of overcrowding and thus less hunting enjoyment. Another contributing factor may have been the availability of electronic licenses, enabling hunters to delay purchase until they assessed bear visitation to their baits and hence probable hunting success.

Despite concern over this trend, harvests have remained high and apparently sufficient to stabilize the bear population at an acceptable level (nuisance complaints have remained low). Bear population estimates, however, have a wide degree of uncertainty, so caution must be exercised in interpreting trends. Moreover, trends in age structure and reproductive rates suggest that despite relative stability in overall population size, population composition continues to change, which may inevitably lead to unpredictable changes in numbers. Continued monitoring of this population and the factors impacting it are hence warranted.

${ }^{\text {a }}$ Quota area established in 1982. No-quota area established in 1987. Surplus licenses from undersubscribed quota areas sold beginning in 2000; originally open only to unsuccessful permit applicants, but beginning in 2003, open to all. Total licenses $=$ quota + quota surplus + no-quota + military (no permit needed).
${ }^{\text {b }}$ Quota licenses bought (including surplus)/permits available, or licenses bought (prior to surplus)/permits issued (permits issued more relevant for years when some areas were undersubscribed; see Table 3).
${ }^{c}$ Number of licensed hunters x percent of license-holders hunting. Percent hunting is based on data from bear hunter surveys conducted during 1981-91, 1998 (86.8\%), and 2001(93.9\%).
${ }^{\text {d }}$ Harvest estimated from 2993 tallied registration + 347 lost registration data (includes 137 estimated from the ratio of envelopes received without matching registration data)..
${ }^{e}$ Sex ratio as reported by hunters; hunters classify about $10 \%$ of female bears as males, so the actual harvest has a lower $\% \mathrm{M}$ than shown here. In good food years, the harvest is more male-biased.
${ }^{f}$ Success rates in 2001-2004 were calculated as number of successful hunters/total hunters, rather than bears killed/total hunters, because hunters could take 2 bears. This was complicated even more in 2005 because the total harvest was estimated (footnote d), and for the first time, hunters could take 1 bear in the quota area plus 2 bears in the no-quota area. From the registration tally and tooth envelopes received ( $\mathrm{n}=3203$ ), 51 hunters took 2 bears ( 2 hunters took 1 quota and 1 NQ bear) and 1 hunter took 3 bears ( 1 quota, 2 NQ).

${ }^{\text {a }}$ Harvest data were obtained from registration slips (or electronic registration, especially in 2005) and tooth envelopes (submitted by hunters). The following table shows the number of tooth envelopes that had no corresponding registration slip. These bears were apparently registered (tooth envelopes were available only at registration stations), but the data were lost.

| Year | Quota area | No-quota area |
| :---: | :---: | :---: |
| 2000 | 39 | 16 |
| 2001 | 56 | 7 |
| 2002 | 46 | 7 |
| 2003 | 84 | 13 |
| 2004 | 96 | 39 |
| 2005 | 179 | 31 |

[^12]${ }^{\text {b }}$ Some registration data were lost from bears registered at 83 different registration stations (tooth envelopes received with no corresponding registration data). The minimum percent lost $=$ (known number of unmatched envelopes)/(total registration tally + total unmatched envelopes). The actual percent loss is higher because only $68 \%$ of hunters turned in envelopes.
${ }^{\text {c }}$ The estimated registered harvest, including those in which registration data were lost and no tooth envelope was received (Table 1, footnote d). Record harvest for BMU 11.
${ }^{\mathrm{d}}$ Some hunters with no-quota licenses hunted in the quota area. Some were drawn for the quota area but received NQ licenses. Others hunted in the wrong area purposefully or out of ignorance. All these are tallied in the area where they actually killed a bear ( $n=15$ in 2005). Otherwise, the tally represents the number of bears killed by hunters who had licenses for the indicated area, even if they killed a bear in another BMU.

Table 5. Bear hunting success (\%) by BMU, measured as the registered harvest (excluding second bear) divided by the number of licenses sold ${ }^{\text {a }}$, 2000-2005.

${ }^{\text {a }}$ Harvest/licenses instead of harvest/hunters because BMU-year-specific estimates for the rate of hunting by licensed hunters are unreliable. Statewide estimates of harvest/hunters are presented in Table 1.
${ }^{\mathrm{b}}$ For 2005, estimated registered harvest was used instead of known registered harvest due to a large loss of registration data.
${ }^{c}$ Percent of successful hunters that shot 2 bears; $2^{\text {nd }}$ bear is not included in the calculation of hunting success. The taking of 2 bears was legal statewide in 2001, but only in the no-quota area in 2002-2005. Three people took bears in both quota and NQ areas in 2005.
${ }^{\text {d }}$ Although BMU 11 had a record harvest, there is no way to split BMUs 11 and 52 to examine hunting success because the number of hunters in each area is unknown (a single NQ license covers both BMUs.

Table 6. Cumulative bear harvest (\% of total harvest) by date, 1990-2005.

${ }^{a}$ The large proportion of the harvest taken late in the season in 1996 and 2002 (e.g., >10\% in October) was related to the high abundance of food in those years.

Figure 1. Bear management units (BMUs or areas) within the Minnesota bear range. Within the primary bear range (shown in white) license numbers are limited by a quota. Hunters can hunt in only one area, except with a no-quota license they can hunt anywhere in the shaded zone (and beginning in 2005 hunters could posses both a no-quota and quota area license).

Figure 2. Number of Minnesota bears actually killed versus the number predicted killed based on fall food abundance and hunter numbers. Prediction for 2005 was from 1984-2004 regression ( $\mathrm{R}^{2}$ $=0.88$ ).

Figure 3. Population estimates ( $\pm 95 \%$ Confidence Interval) of Minnesota black bears from tetracyclinemarking. Three clusters of points correspond with different estimates for the years of marking, 1991, 1997 \& 2002. Curve approximates probable population trajectory.

Figure 4. Statewide harvest age structure for Minnesota black bears showing proportion of each sex in age category. Increasing proportion of yearling bears of each sex (and corresponding decline in the proportion of medium-aged females) are shown by regression lines.

Figure 5. Year-specific cub production of bears near the center of the Minnesota bear range measured as the proportion of denning adult (4+ year-old) females with cubs and cubs/female. Sample sizes vary from 5-25 adult females monitored per year (mean = 16). Dens are visited in March, so 2006 data are included.

# 2005 Minnesota Moose Harvest 

Mark S. Lenarz, Forest Wildlife Populations \& Research Group

## INTRODUCTION

Each year, a limited number of permits are issued that allow Minnesota residents to hunt moose. The following report is intended to document the number of hunters applying for permits, the number of permits issued, a hunting party's chance of receiving a permit, hunter success rate, and a breakdown of the harvest by hunting zone (Figure 1). Information on permit numbers and moose harvested by members of the 1854 Authority or Fond du Lac band of Lake Superior Chippewa within the 1854 Ceded Territory is also provided.

## METHODS

All successful State hunters are required to register their moose at one of 8 registration stations and provide information on the location where they killed their moose, date of kill, and sex of moose harvested.

## RESULTS

In 2005, 219 moose were harvested in northeastern Minnesota. No season was held in northwestern Minnesota. The State of Minnesota licensed 284 hunting parties and hunters killed 163 moose including 136 bulls and 27 cows (Table 1). Data on the number of permits offered, chance of being selected for a permit, hunter success, and percent bulls in the harvest, are also listed (Table 1). The 1854 Authority issued 50 hunter permits and 4 subsistence permits. A total of 22 bulls and 6 cows were killed (including 3 animals taken with subsistence permits). The Fond du Lac band issued a total of 83 permits and the preliminary harvest (as of $11 / 10 / 2005$ ) was 28 moose ( 19 bulls and 9 cows). The Fond du Lac season closes 12/4/2005.

## DISCUSSION

The success rate of State hunters in 2005 was $57 \%$ and represents an all time low for moose hunts in northeastern Minnesota (Tables 1 and 2). In 2004, the success rate for State hunters was $62 \%$. The success rate for 1854 Authority was $52 \%$. The preliminary success rate for the Fond du Lac band was $34 \%$, as of $11 / 10 / 2005$.

# 2005 Trapper Harvest Survey 

Margaret Dexter, Wildlife Policy and Research Unit

## INTRODUCTION

The Minnesota Department of Natural Resources, Wildlife Policy and Research unit annually conducts a survey of trapper license holders. Annual harvest estimates from survey data provide guidance for future trapping regulations and season structure.

## METHODS

The Wildlife Policy and Research unit requests a list of all active trapper license holders from the Electronic License System database in late February. The sample consisted of all valid Regular, Junior and Non-resident Trapper License holders. For the 2005-06 trapping season there were 5,456 Resident Regular Trappers, 704 Resident Junior Trappers, and 3 Nonresident (MN landowners) Trappers surveyed. Of the 6,163 valid licenses, 6060 had usable addresses for purposes of the survey.

Trappers that returned the survey questionnaire within three weeks were marked returned and eliminated from follow-up mailings. Follow-up mailings were sent to non-respondents at intervals of three weeks. There were three follow-up mailings to non-respondents.

Completed and returned questionnaires were checked for completeness, consistency, and biological practicability. Cards were marked with numeric county codes corresponding to the trapper's written information. Data from each usable card was converted to an electronic database. Data were checked for errors, duplicate responses, and /or missing data. The following is a list of assumptions made in data coding:

1) If an individual checked the box indicating (s)he did not trap, but harvest information was provided, it was assumed that the individual did trap.
2) If a range was given for "number of days trapped" or "number of animals harvested", the median of the range, rounded to the nearest even integer was recorded.
3) If a trapper indicated spending time trapping for a species, but left "number trapped" blank, the \# trapped was entered as missing data.
4) If a trapper indicated taking a species, but left "number of days trapped" blank, then "number of days trapped" was recorded as missing data.
5) If more than one county was indicated for "county trapped in most", the first county listed was recorded. However, if the several counties listed were indicated to apply to all species trapped, then counties were recorded in sequential order in relation to species hunted.
6) If "county trapped in most" was left unanswered or not legible, the county was recorded as missing data.

Data from all usable cards were tabulated and statistically analyzed by the St. Paul staff, using SAS statistical analysis software programs.

## RESULTS

Attached are the survey results showing survey response rate, estimated number of trappers, estimated take per trapper, and estimated harvest statewide (Tables $1-5$ ).

Table 1. Trapper response to mail surveys, 1980-81 through 2005-06.

| Year | Number mailed | Number not delivered | Delivered questionnaires completed and returned |  |
| :---: | :---: | :---: | :---: | :---: |
|  |  |  | Number | Percent |
| 1980-81 | 1,345 | 110 | 1,072 | 86.8 |

${ }^{\text {a }}$ Includes data for all seasons from October through April of years indicated.
${ }^{\mathrm{b}}$ Separate licenses were issued for juveniles (13-17 years old) and adults (18 and older), beginning in 1982. As of March 3, 2006 6,163 trapping licenses were sold in 2005704 (11.4\%) were juvenile licenses and $5,456(88.5 \%)$ were adult licenses $3(<1 \%)$ were Nonresident (MN Landowner) licenses. Duplicate licenses excluded.
${ }^{\text {c }}$ Based upon trappers' responses to mail surveys. ${ }^{\mathrm{d}} 1$ is any number which rounds to $1 .<1$ is any number which is $<0.5$.
${ }^{e}$ Registered harvest for bobcat includes animals taken by hunting. ${ }^{\mathrm{f}}$ Raccoon and red fox seasons changed to year round beginning May 1994.
${ }^{\mathrm{g}}$ Lynx (1984) and Eastern spotted skunk (1996) listed as Special Concern and threatened species (respectively) and are fully protected.

# Minnesota Fur Buyers Survey For the 2005-06 Hunting and Trapping Season 

Conrad Christianson, Wildlife Furbearer / Depredation Program Consultant Margaret Dexter, Wildlife Policy and Research Unit

## INTRODUCTION

Fur buyers are individuals licensed by the State of Minnesota to buy and sell raw fur. They are required to keep complete records of all transactions and activities related to buying, selling, and disposing of raw furs. Each year buyers are sent a questionnaire asking them to submit information regarding the "average" price they paid to trappers for various furbearers the previous season.

## METHODS

In February 2006, questionnaires were mailed to the 32 licensed furbuyers in Minnesota. The survey asked them to report the number and type of fur purchased from Minnesota trappers and hunters in 2005-06 and the "average price" paid to those hunters and trappers based on all furs purchased. A total of 30 usable surveys were received, for a return rate of $93.8 \%$.

Calculations of average pelt price for each species (Table 1) were weighted according to the number of pelts purchased by each buyer. Average pelt prices for the past 15 years are summarized in Table 2. Total estimated value of the furbearer harvest to trappers and hunters in 2005-06 was $\$ 1,593,737$, an increase of $62.5 \%$ from 2004-05.

## RESULTS

Survey summaries are presented in the following tables.
Table 1. Minnesota fur prices as reported by licensed fur dealers, 2005-06.

| Species | Number Buyers | Number Pelts | Minimum Price | Maximum Price | Weighted Mean |
| :--- | ---: | ---: | ---: | ---: | ---: |
| Muskrat | 19 | 36308 | $\$ 2.00$ | $\$ 4.50$ | $\$ 2.81$ |
| Mink, female | 17 | 3759 | $\$ 5.50$ | $\$ 13.95$ | $\$ 10.23$ |
| Mink, male | 18 | 5262 | $\$ 9.00$ | $\$ 18.00$ | $\$ 14.29$ |
| Raccoon | 19 | 33465 | $\$ 6.00$ | $\$ 12.00$ | $\$ 9.61$ |
| Red fox | 18 | 2038 | $\$ 11.00$ | $\$ 20.00$ | $\$ 16.96$ |
| Gray fox | 14 | 259 | $\$ 8.00$ | $\$ 20.00$ | $\$ 15.00$ |
| Coyote | 16 | 3108 | $\$ 8.00$ | $\$ 20.00$ | $\$ 13.57$ |
| Bobcat | 9 | 185 | $\$ 80.00$ | $\$ 120.00$ | $\$ 95.74$ |
| River Otter | 16 | 1287 | $\$ 50.00$ | $\$ 100.00$ | $\$ 88.89$ |
| Beaver, fall | 17 | 14625 | $\$ 7.75$ | $\$ 20.00$ | $\$ 14.48$ |
| Beaver, spring | 15 | 18698 | $\$ 9.00$ | $\$ 22.00$ | $\$ 16.49$ |
| LT weasel | 4 | 55 | $\$ 2.00$ | $\$ 10.00$ | $\$ 2.56$ |
| ST weasel | 10 | 533 | $\$ 1.00$ | $\$ 3.50$ | $\$ 2.60$ |
| Striped skunk | 11 | 316 | $\$ 1.00$ | $\$ 6.00$ | $\$ 3.77$ |
| Badger | 12 | 143 | $\$ 6.00$ | $\$ 20.00$ | $\$ 13.40$ |
| Opossum | 9 | 372 | $\$ 0.50$ | $\$ 2.00$ | $\$ 1.40$ |
| Fisher, male | 14 | 501 | $\$ 30.00$ | $\$ 60.00$ | $\$ 36.03$ |
| Fisher, female | 14 | 435 | $\$ 25.00$ | $\$ 65.00$ | $\$ 31.46$ |
| Marten, male | 11 | 391 | $\$ 32.60$ | $\$ 50.00$ | $\$ 37.47$ |
| Marten, female | 10 | 300 | $\$ 30.00$ | $\$ 38.20$ | $\$ 31.53$ |
| Deer Hides | 17 | 62449 | $\$ 3.00$ | $\$ 5.00$ | $\$ 4.14$ |
| Bear Hides | 7 | 101 | $\$ 30.00$ | $\$ 41.00$ | $\$ 39.30$ |

Grand Rapids, MN 55744
(218) 327-4432

# Registered Furbearer Harvest Statistics 2005-06 Report 

John Erb, Forest Wildlife Populations and Research Group

## INTRODUCTION

Monitoring harvest is an important component of population management for many wildlife populations. For many species, harvest represents a large proportion of overall mortality. Obtaining harvest information can be useful for documenting changes in the distribution and abundance of animals, as well as the effects of changes in harvest seasons, harvest techniques, and habitat. The level of detail or accuracy necessary in harvest information may vary across species, depending on such factors as density, harvest pressure, habitat sensitivity of the species, and reproductive potential.

In Minnesota, detailed harvest information is collected on 4 carnivores - fisher, marten, bobcat, and river otter. These species have lower reproductive potential, naturally occur at low to moderate densities, have comparatively 'restricted' distributions, and/or may be more subject to effects of habitat change. Hence, detailed harvest information is desirable to help ensure sustainable populations. For approximately the past 28 years, such data has been collected for these species.

## METHODS

Currently, harvest of these species is allowed in approximately the northern $60 \%$ of the state. Fur-harvesters are required to bring pelts from harvested animals (fisher, marten, bobcat, otter) in to fur registration stations within 48 hours of the close of the season. Upon registration, information is collected on the sex, date, and location (township) of the harvested animal, and the pelt is tagged to verify it has been registered.

## RESULTS

All harvest summaries are provided in the following tables.
NOTE: This report does not include tribal harvests, or any confiscations.

Table 1. Registered furbearer harvests and total permits ${ }^{\mathrm{a}}$ issued, 1981-2005.

${ }^{\text {a }}$ Prior request tags and permits were required beginning in 1985 for marten and in 1986 for fisher and otter. No possession tags or prior permits have been required for bobcat, and prior request tags and permits were no longer required for fisher, marten, or otter starting in 2001-02.

| $2000-01$ | $206(32)$ | $122(19)$ | $108(17)$ | $201(32)$ | 637 |
| $2001-02$ | $147(23)$ | $175(27)$ | $138(21)$ | $187(29)$ | 647 |
| $2002-03$ | $253(33)$ | $147(19)$ | $122(16)$ | $241(32)$ | 763 |
| $2003-04$ | $269(27)$ | $201(20)$ | $152(16)$ | $361(37)$ | 983 |
| $2004-05$ | $302(25)$ | $235(19)$ | $182(15)$ | $498(41)$ | 1217 |
| $2005-06$ | $291(27)$ | $213(20)$ | $186(17)$ | $386(36)$ | 1076 |

[^15]
[^0]:    ${ }^{1}$ Includes DNR and Tribal harvests
    ${ }^{2}$ Estimated from population model; includes estimated accidental harvests of $10 \%$.
    ${ }^{3}$ Average pelt price based on a survey of in-state fur buyers only.

[^1]:    ${ }^{1}$ Combined limit since 1999 of any combination of marten and fisher totaling the specified limit, except in 1999 where fisher portion of limit could only be 2.
    ${ }^{2}$ Includes DNR and Tribal harvests
    ${ }^{3}$ Estimated from population model, includes estimated accidental harvests of 22\% 1977-1992, and 11\% in 1993-1999
    ${ }^{4}$ Average pelt price based on a survey of in-state fur buyers only.

[^2]:    ${ }^{1}$ Combined limit since 1999 of any combination of fisher and marten totaling the specified limit, except in 1999 where fisher portion of limit could only be 2.
    ${ }^{2}$ Includes DNR and Tribal harvests
    ${ }^{3}$ Estimated from population model; includes estimated accidental harvests of $40 \%$ in 1985-1987 and 1991, 20\% in 1988-1990 and 1992-1998, and 15\% from 1999-present.
    ${ }^{4}$ Average pelt price based on a survey of in-state fur buyers only.

[^3]:    ${ }^{1}$ Includes DNR and Tribal harvests
    ${ }^{2}$ Estimated from population model. Incl. estimated accidental harvests of $30 \%$ to $1991,22 \%$ from 1992-2001, and $15 \%$ after 2001.
    ${ }^{3}$ Weighted average of spring (beaver only) and fall prices based on a survey of in-state fur buyers.

[^4]:    ${ }^{1}$ Type II-V, correction factor from $1989(123,000 / 203,000=0.606)$ used to adjust $1968-88$ pond numbers. Ponds counted on 0.125 mile wide transect after 1988.

[^5]:    ${ }^{1}$ Unad. PI - unadjusted population index, VCF - Visibility Correction Factor, PI - adjusted population index, SE - standard error.
    ${ }^{2}$ Calculated from data in Waterfowl breeding ground survey reports, 1968 through 1972, from Minn. Game Res. Quarterly Reps. 1968 and 1969 other duck VCF is total duck VCF.
    ${ }^{3}$ Calculated from data in Maxson and Pace (1989).

[^6]:    ${ }^{1}$ Unad. PI - unadjusted population index, VCF - Visibility Correction Factor, PI - adjusted population index, SE - standard error

[^7]:    ${ }^{a}$ Includes resident and non-resident licenses, and excludes duplicate licenses.

[^8]:    ${ }^{\text {a }}$ Harvest estimates not adjusted for memory/exaggeration bias.

[^9]:    ${ }^{\mathrm{a}}$ Success rate not adjusted for non-participants.

[^10]:    ${ }^{\text {a }}$ Huntable habitat is forest cover buffered by 50 meters, with non-huntable areas (e.g., lakes, cities) removed.

[^11]:    Does not include free landowner licenses Based on total license sales - does not include all-season deer

[^12]:    * Record high harvest in BMU 11 in 2005.

[^13]:    * Number of 2 , 3 , and 4 person parties.

[^14]:    Product of categories above may not equal total harvest due to some unknown name/license numbers

[^15]:    * Product of categories above may not equal total harvest due to some unknown name/license numbers
