**CLASSIFICATION, INDICATOR VALUE, AND
REGIONAL DIFFERENTIATION
OF BRYOPHYTE SPECIES
IN MINNESOTA'S CALCAREOUS FENS
and
VALIDATION OF CALCAREOUS FENS
Update June 2004**

Calcareous-Fen Indicators and Regional Differentiation

The following classification of bryophytes occurring in Minnesota's calcareous fens (CF) is based on a ranking of their importance value (IPV, Table 1). There are a total of 416 bryophyte species in Minnesota with detailed habitat information (fully surveyed ecotopes, see Janssens 2002), and 128 of these occur in calcareous fens. The total number of Minnesota ecotopes I have surveyed for bryophytes equals 1128, of which 124 are calcareous or extreme rich-fen habitats.

In addition, I have listed in Table 1 the regional relative abundance for each species. Three sub-regions are recognized for the prairie region (Aaseng et al. 1993): the NW, SW, and SE. The boreal and central region is not further differentiated here, because the distinction between the two areas is still being investigated (Aaseng, pers. comm.).

Figure 1 and perusal of the species list (Table 1) suggests to me that there is a reasonable division in **obligate and near-obligate** calcareous fen indicators (OB) with an IPV above 1.000 (17 species), **facultative** (FA) calcareous fen species with an IPV between 0.100 and 1.000 (15 species), and the remaining 96 species with an **occasional** (OC) occurrence and an IPV of <0.100. In Table 2 I have summarized the most frequent species and their regional preference.

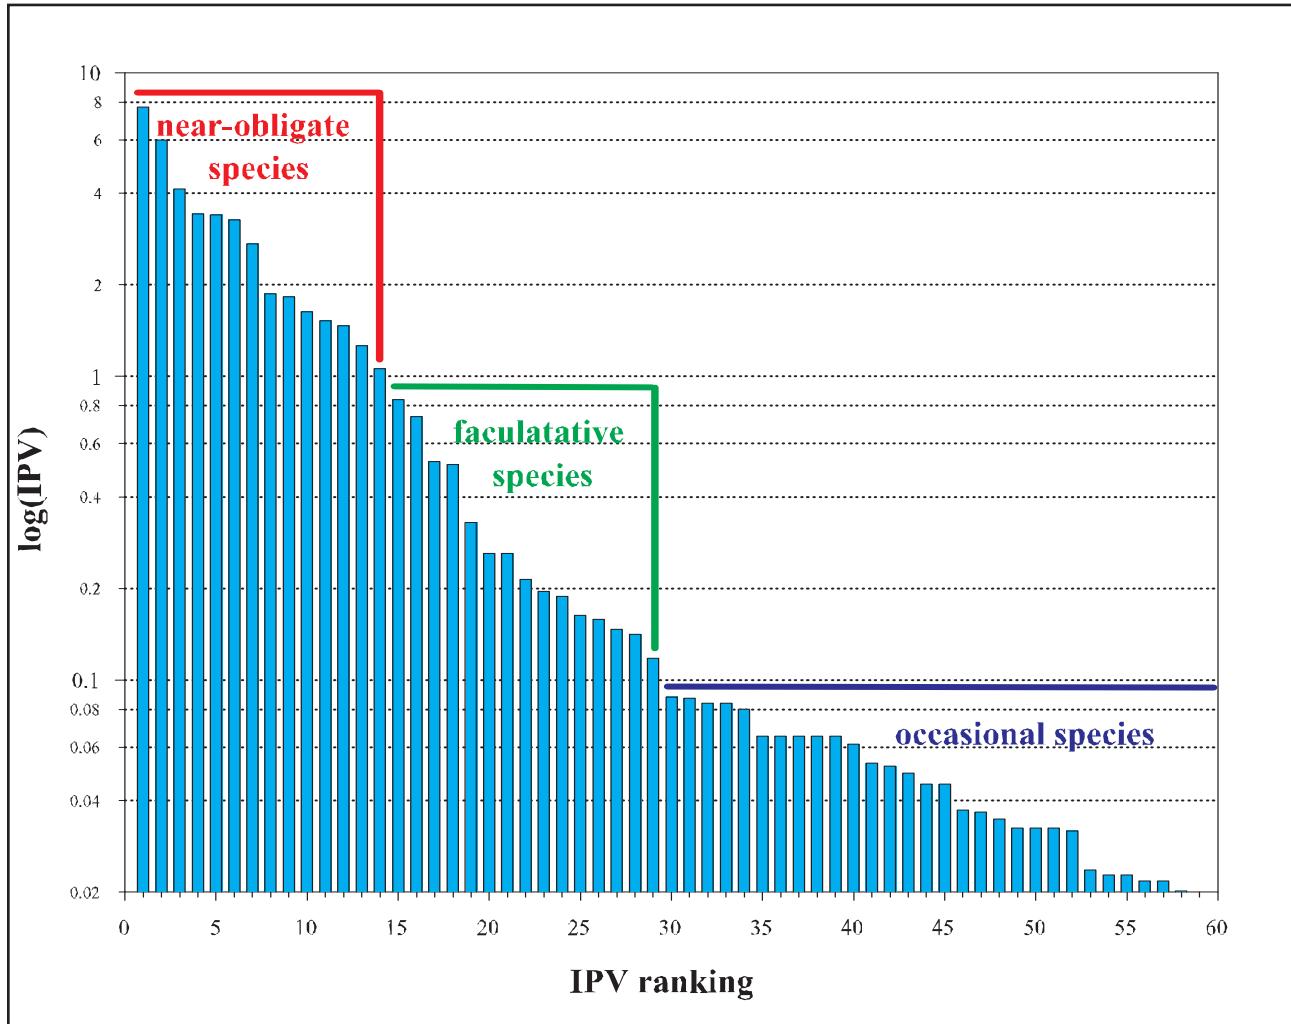

Figure 1. Most common bryophytes occurring in calcareous fens, ranked by descending IPV (to .02).

Table 1. Ranking of bryophyte species occurring in Minnesota's calcareous fens in order of descending IPV ($CF_{freq}^2/nonCF_{freq}$). I designated species with an IPV >1.000 as **obligate and near-obligate** indicators, with an IPV between 0.100 and 1.000 as **facultative** indicators, and those with an IPV <0.100 as **occasional** species. The column labeled 'n CF' lists the number of calcareous-fen ecotopes in which the species occurs (out of a total of 124), 'n tot' the total number of surveyed ecotopes in Minnesota where the species has been found (out of a total of 1128). The values in the columns labeled 'CFB', 'CFPnw', 'CFPsw', and 'CFPse' are the relative abundances of the species in the extreme-rich fens of boreal (including central) forested region, and the calcareous fens of the NW, SW, and SE prairie sub-regions. The relative abundance is calculated as the % ratio of the number of collections for the species over the total number of all calcareous-fen bryophyte collections (n CFB = 928, CFPnw = 1806, CFPse = 1332, and CFPsw = 2339).

Validation of Minnesota Calcareous Fens:

I have assigned an arbitrary value of 25 points to the **obligate and near-obligate** calcareous fen indicators, 5 points to the **facultative** species, and 1 point to the **occasional** species. Adding these species scores for each one of the calcareous fens of Minnesota with bryophyte surveys, the following validation is obtained (Table 3):

Table 3. Validation of the calcareous-fen localities of Minnesota based on the presence of bryophyte indicators. The *a priori* list of calcareous prairie fens studied has been provided by the Minnesota Department of Natural Resources (Aaseng *et al.* 1993 and pers. comm.) and the typing of the sites as calcareous fens is based on an independent assessment using vascular-plant indicators, and soil and water-chemistry characteristics (J.H. Leete and W.R. Smith, pers. comm.). Additional sites assessed as calcareous fens, added after the bryophyte-indicator has been set up (Table 1), are marked by an *. This table can be used as part of the assessment to evaluate non-listed sites for their identification and potential as calcareous fens. First a regional ranking (r) is given, and then an overall ranking (R) of all Minnesota calcareous fens.
