Appendix 295-G: Drill Log Comment Field

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 15464 DDH#: 306 P295 File #: DH2951-035

Comments: Laminated carbonate, magnetite, silicate iron formation. Core is fairly magnetic, and is somewhat phyllitic. One small quartz vein present. Only 15 cm. of core remains. Analysis on jar label indicates an analysis of 23.47% Fe, and 7.70% Mn.

Unique DDH#: 15465 DDH#: 307 P295 File #: DH2951-036

Comments: Laminated carbonate, magnetite, silicate iron formation, with surface(?) oxidation (hematitic) in the upper portion. Core is fairly magnetic, and locally (especially coarser portions) calcareous. One small quartz vein present. Only 25 cm. of core remains, with 5 jars of cuttings or crushed core. Analyses on jar labels indicates 22.63% Fe and 9.02% Mn for 55-60'; 22.15% Fe and 6.05% Mn for 60-65'; and 21.01% Fe and 7.57% Mn for 48-55'. Crushed core colors are 10R 3/4 (48-55') and 5Y 5/2 to 10YR 6/2 (55-65').

Unique DDH#: 15466 DDH#: 308 P295 File #: DH2951-037

Comments: Laminated carbonate, magnetite, silicate iron formation. Core is fairly magnetic. Samples consist of 6 cm. of core, and 2 jars of cuttings or crushed core. Analyses on jar labels indicates 23.61% Fe and 7.13% Mn for 55-60'; and 26.58% Fe and 6.38% Mn for 49-55'. Crushed core colors are 5Y 5/2 to 5Y 2/1. Schistosity is moderately developed, and intersects the bedding at a high angle.

Unique DDH#: 15467 DDH#: 309 P295 File #: DH2951-038

Comments: Samples limited to 13 cm of core and 1 bottle of crushed core. Rock is dark brown (goethitic?) ferruginous phyllite and siltstone. Crushed core color is 5YR 5/2 (58-60').

Unique DDH#: 15468 DDH#: 310 P295 File #: DH2951-039

Comments: Most of samples are crushed core. Identifiable rock fragments indicate chert hematite goethite magnetite iron formation. Some quartzite may also be present, with recrystallization making identification difficult. Calcite, vein quartz, and black oxide (Mn oxides?) is present in a number of samples. Jar labels indicate analyses with up to 49.55% Fe (165-170') and 14.26% Mn (115-120'). Crushed core colors are 5YR 3/2 (45-50, 120-125, 130-135, 150-175'), 5YR 4/4 (58-70, 95-100'), 10R 4/4 (70-75, 80-85'), 10YR 4/2 (85-90, 105-115'), 5YR 3/4 (90-95, 100-105, 115-120, 135-145'), 5YR 4/2 (125-130'), 10YR 3/2 (145-150'), 10R 3/4 (175-180'), and 10R 3/2 (180-185').

Unique DDH#: 10753 DDH#: 18135 P295 File #: DH2951-040

Comments: Dark green fine- to coarse grained altered "metagabbro". Variable textures look locally fragmental(?). Surface weathering to clays, limonite and hematite along fractures. Trace disseminated pyrite, and local deuteritic(?) alteration.

Unique DDH#: 10754 DDH#: 18138 P295 File #: DH2951-041

Comments: Carbonate silicate magnetite iron formation with local oxidation to hematite, limonite, and goethite. Core may be deeply weathered, but these effects are difficult to separate from other (hydrothermal?) alteration. Quartz, grey hematite, carbonate and pyrite veins occur locally with local disseminated pyrite elsewhere. The iron formation in 283-300 also contains conformable pyrite and graphite. Local brecciation and alteration (300-315' especially) may have created "metabasalt" looking rocks. Greenish chalcedony vein at 284'. Goethitic portions have coarser secondary magnetite porphyroblasts.

Unique DDH#: 10755 DDH#: 18144 P295 File #: DH2951-042

Comments: Altered metagabbro. Locally clayey. Local deuteritic(?) alteration. Hairline fractures-shears contain black oxides, pyrite, carbonate and quartz (with associated limonitic alteration?). Variable textures look locally fragmental.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 15469 DDH#: S118 P295 File #: DH2951-043

Comments: Core is white quartzite with minor oxide grains and Liesegang banding. Rock contains 20-30% white grains (altered feldspars? or kaolinite?). Mn oxide and some iron oxides are fracture related as is muscovite locally. Identifiable crushed core fragments are predominantly siliceous clastic rock, with minor iron oxides. Crushed core colors are 5YR 6/4 (77-80'), 10YR 6/4 (80-85'), 5YR 7/4 (85-90, 100-104, 119-124'), 10YR 7/4 (90-95'), 10YR 8/4 (95-100'), 10YR 7/2 (104-109'), and 10YR 8/2 (109-119').

Unique DDH#: 15470 DDH#: S124 P295 File #: DH2951-044

Comments: Interbedded quartzite (and recrystallized chert?) and goethite hematite iron formation. Oxides appear to be secondary (alteration or deep weathering?). Local black pisolithic Mn oxides(?) at 222'. Quartz veins are locally fractured to brecciated above 252'. White chalcedony veins occur locally. Fragmental samples are probably overburden to 110'. Crushed core colors are 5YR 4/4 (97-100, 135-145, 150-160'), 5YR 6/4 (100-105'), 10YR 7/4 (105-110'), 5YR 6/6 (110-115, 125-130'), 5YR 5/6 (115-125'), 5YR 5/5 (130-135'), 10R 3/6 (145-150, 160-165, 198-222'), 5YR 4/6 (165-170'), 5YR 3/4 (170-175'), 10R 3/4 (175-195'), and 10R 4/6 (195-198).

Unique DDH#: 15471 DDH#: S126 P295 File #: DH2951-045

Comments: Quartzite with argillite patches over limonitic goethitic hematitic iron formation. Argillite may be clastic dikes(?), soft sediment deformation related or deformed intraclasts. Local quartz veins and brecciation. Crushed core colors are 10YR 7/4 (72-79, 90-95'), 10YR 6/4 (79-85'), 10YR 7/2 (85-90'), 10YR 6/6 (95-100'), 10R 3/6 (100-105'), 5YR 4/6 (105-110'), 5YR 6/4 (107-115'), 5YR 4/4 (110-125'), and 10YR 3/4 (125-135').

Unique DDH#: 15472 DDH#: S1042 P295 File #: DH2951-046

Comments: Relatively little core. Goethitic hematitic iron formation with quartzite, recrystallized chert and ferruginous siltstone. Local brecciation (tectonism or solution collapse). Local carbonate. Minor sulfate within 297-301', 310-315', 325-330', 345-350'. The interval 255-260 contains many quartz vein fragments. Crushed core colors are 10R 3/4 (72-85, 100-105, 110-120, 122-149, 150-161, 165-170, 187-195, 208-220, 225-235, 265-275, 280-289, 295-315, 320-345, 350-355'), 10R 5/4 (85-100'), 10R 4/6 (88-100, 187-208, 235-265, 276-285, 289-295, 355-360'), 5YR 4/4 (105-110, 120-122, 360-370, 400-405, 410-420, 425-428'), 5YR 3/4 (122-135, 161-187, 375-395, 405-410, 420-425'), 5YR 2/6 (135-140, 149-150'), 10R 3/6 (222-225, 370-375'), and 5R 3/4 (315-320, 345-350').

Unique DDH#: 15473 DDH#: S1043 P295 File #: DH2951-047

Comments: Little drill core. Goethitic hematitic iron formation with quartzite, recrystallized chert. Grey hematite may be replacing the siliceous rock. Minor sulfate or kaolin within 25-30, and 95-100'. Recognizable fragments in crushed core are usually grey hematite. Crushed core colors are 10R 3/4 (0-5, 10-15, 25-35, 49-55 blast, 65-80, 85-90'), 5YR 3/4 (5-10, 49-60'), 10R 4/4 (15-20, 35-49, 60-65, 80-85'), and 5R 3/4 (90-100').

Unique DDH#: 15474 DDH#: S1044 P295 File #: DH2951-048

Comments: Goethitic hematitic iron formation and siliceous siltstone. Grey hematite and goethite may be replacing the siliceous rock. Few recognizable fragments in crushed core. Goethitic portions often vuggy to rubble, and appear to be sinter(?) related. Crushed core colors are 10R 4/4 (0-10, 30-35, 45-50, 60-65'), 10R 3/4 (10-15, 40-45, 65-70, 90-95'), 5YR 4/4 (15-30, 35-40, 80-90'), 10R 4/6 (50-55'), 5YR 3/4 (55-60, 70-75'), and 7R 3/4 (75-80').

Unique DDH#: 10963 DDH#: 306 P295 File #: DH2951-049

Comments: Slightly phyllitic, graphitic, pyritic siltstone. Contains 1-5%? pyrite.

Unique DDH#: 10756 DDH#: 18145 P295 File #: DH2951-050

Comments: Variably altered metagabbro. Core generally clayey and limonitic. Igneous textures almost destroyed. Locally intensely weathered along fractures. Contains local limonitic vugs (deuteric?). Scattered thin quartz calcite veinlets.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10761 DDH#: 18226 P295 File #: DH2951-051

Comments: Hematitic kaolinitic claystone over laminated carbonate silicate magnetite iron formation. Weathering effects decrease downwards. Contains siderite calcite veins. May contain altered plagioclase laths within 290-295'.

Unique DDH#: 10752 DDH#: 18132 P295 File #: DH2951-052

Comments: Clayey saprolite apparently developed on siliceous pyritic breccia over carbonate silicate magnetite iron formation with carbonate quartz pyrite veins. Breccia hydrothermal(?)

Unique DDH#: 10749 DDH#: 18427 P295 File #: DH2951-053

Comments: Saprolite developed on tuffaceous(?) siltstone with oxides and pyrite, over fragmental graphitic sulfide siltstone with chert or quartz veins; over variably goethitic and brecciated carbonate silicate magnetite iron formation. Porphyroblastic magnetite locally developed.

Unique DDH#: 10750 DDH#: 18430 P295 File #: DH2951-054

Comments: Saprolic material developed on siltstone breccia with local iron formation, over non brecciated counterparts(?) of pyritic siliceous siltstone or chert, and chert carbonate silicate magnetite iron formation. These are over a mafic-intermediate volcanic or dyke. This is locally fragmental.

Unique DDH#: 10762 DDH#: 18228 P295 File #: DH2951-055

Comments: Altered weathered metagabbro, and perhaps minor iron formation at the top. Limonite and clay alteration decrease downward.

Unique DDH#: 10751 DDH#: 18435 P295 File #: DH2951-056

Comments: Variably weathered and brecciated carbonate silicate magnetite iron formation with minor chert, graphite and sulfide chemical sediment; and goethitic hematitic iron formation (sinter-like?). Brecciation (faulting?) most common in 275-285'.

Unique DDH#: 10757 DDH#: 18146 P295 File #: DH2951-057

Comments: Ferruginous clayey siltstone or argillite over carbonate silicate magnetite iron formation over brecciated volcanoclastic rock. Volcanoclasts to 5 cm. Probably intermediate. Brecciation scattered throughout the core. Clayey upper material has blue clay partings locally.

Unique DDH#: 10758 DDH#: 18218 P295 File #: DH2951-058

Comments: Rubbley hematitic goethitic clayey saprolitic rock over carbonate silicate magnetite iron formation with quartz pyrite veinlets. Minor green blue soft clays. Looks sinter-like locally.

Unique DDH#: 10759 DDH#: 18221 P295 File #: DH2951-059

Comments: Sheared and altered variably limonitic feldspar porphyry (andesitic to trachytic?). The interval 246-249' and 283-284' looks fragmental (tuffaceous?). Local xenoliths occur locally.

Unique DDH#: 10763 DDH#: 18230 P295 File #: DH2951-060

Comments: Limonitic hematitic clayey saprolitic iron formation, intermediate-mafic metatuff over graphitic carbonate siltstone over porphyritic iron silicate chemical sediment (mylonitic?). Local pyrite veining within 390-400'. Deformation and textures make protolith identities uncertain. Neat, strange stuff.

Unique DDH#: 10760 DDH#: 18223 P295 File #: DH2951-061

Comments: Ferruginous siltstone or paint rock over laminated silicate iron formation of mafic derived sediment(?). Locally brecciated, fragmental and mylonitic.

Unique DDH#: 15475 DDH#: S1 P295 File #: DH2951-062

Comments: Locally ferruginous siliceous to argillaceous tuffaceous siltstone. All crushed core samples contain black oxide fragments. Local quartz veining. Crushed core colors are 10R 6/2 (62-65'), 10R 5/4 (65-70, 80-85'), 10R 4/6 (70-80, 85-95'), and 5R 6/2 (95-105').

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 15476 DDH#: S8 P295 File #: DH2951-063

Comments: Locally ferruginous siliceous to argillaceous tuffaceous siltstone. Local quartz veining. Crushed core colors are 10R 5/4 (55-60, 75-85'), 10R 4/4 (60-65'), 10R 4/2 (65-70'), and 10R 5/2 (70-75').

Unique DDH#: 15477 DDH#: S1131 P295 File #: DH2951-064

Comments: Variably brecciated goethite grey hematite martite(?) chert iron formation with quartz goethite veining.

Unique DDH#: 15478 DDH#: S1006 P295 File #: DH2951-065

Comments: Cherty limonitic goethitic iron formation over carbonate silicate magnetite iron formation. Quartz goethite veins have carbonate and minor pyrite. Rock is locally brecciated and folded.

Unique DDH#: 15479 DDH#: S364 P295 File #: DH2951-066

Comments: Limonitic goethite chert iron formation. Vuggy and rubbley textures locally throughout. Slightly magnetic at depth.

Unique DDH#: 15480 DDH#: S346 P295 File #: DH2951-067

Comments: Silty siliceous arenite with poorly developed schistosity. Contains disseminated magnetite grains.

Unique DDH#: 15481 DDH#: S1060 P295 File #: DH2951-068

Comments: Laminated carbonate magnetite silicate iron formation with chert. Scattered veinlets with pyrite. Sulfidation of country rock within 55-60'. Much brecciation and folding.

Unique DDH#: 15482 DDH#: S1054 P295 File #: DH2951-069

Comments: Magnetite hematite goethite iron formation. No location information located, but may show up on maps with DDH's 1050, 1053, or 1060. Slight metamorphic fabric.

Unique DDH#: 15483 DDH#: S1053 P295 File #: DH2951-070

Comments: Recrystallized chert and goethite iron formation over red hematitic paint rock (argillaceous?). Goethitic portion looks vuggy, sinter-like, with hydrothermal brecciation.

Unique DDH#: 15484 DDH#: S1045 P295 File #: DH2951-071

Comments: Goethitic hematitic iron formation (saprolite??), over hematitic argillite, over altered calcareous tuff (29-31'), over ferruginous graphitic argillite. Rare minor white kaolinite or sulfate grains.

Unique DDH#: 15485 DDH#: S1046 P295 File #: DH2951-072

Comments: Core very broken. Goethitic iron formation with minor chert. Local goethite carbonate alteration.

Unique DDH#: 15486 DDH#: S1047 P295 File #: DH2951-073

Comments: Ferruginous phyllite and goethite hematite iron formation. Phyllite may be graphitic, especially toward the base. Iron formation vuggy (hydrothermal alteration activity??).

Unique DDH#: 15487 DDH#: S1048 P295 File #: DH2951-074

Comments: Goethite hematite iron formation over magnetite iron formation with little hematite. Minor quartz goethite veining.

Unique DDH#: 15488 DDH#: S1050 P295 File #: DH2951-075

Comments: Variably brecciated and deformed chert hematite and argillitic rock, over brecciated chert goethite rock over hematitic argillite (paint rock) over laminated chert magnetite iron formation. Goethitic breccia portion may have Mn oxides associated with it (46-50').

Unique DDH#: 15634 DDH#: S361 P295 File #: DH2951-076

Comments: Goethite chert grey hematite limonite iron formation with local brecciation and quartz carbonate goethite red hematite veinlets.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 11639 DDH#: 18600 P295 File #: DH2951-077

Comments: Brecciation and iron oxide alteration down to 160' or so may be fault related, or may be related to surficial weathering with associated solution collapse breccia. Hydrothermal brecciation and alteration is possible, but not probable. Any combination of the above could have occurred. Sulfide contribution of veins from graphitic sediments is unknown.

Unique DDH#: 11661 DDH#: 18400 P295 File #: DH2951-078

Comments: Good bauxitic textures and secondary magnetite are developed in surficially weathered material. Local brecciation may be tectonic solution collapse (not likely) and pseudobrecciation. Some sediments appear to be intraclastic. Replacement by hematite and goethite occurs locally throughout and could be surficial, hydrothermal or a combination.

Unique DDH#: 11641 DDH#: MR-5 P295 File #: DH2951-079

Comments: Rock is a deformed clastic sediment with quartz, dolomite, and sericite. This could be feldspar alteration products which may have resulted from a tuffaceous component.

Unique DDH#: 15489 DDH#: S1020 P295 File #: DH2951-080

Comments: Iron oxides vary and it is difficult to sort out probable methods controlling genesis of different portions (chemical sediment versus weathering versus hydrothermal alteration.) Iron rich and graphite rich chemical sediments merge in the basal 20'. Goethitic portion in 225-240' is vuggy with minor carbonate veins and may be some kind of sinter related material.

Unique DDH#: 15490 DDH#: 280 P295 File #: DH2951-081

Comments: Vein and alteration mineralogy is complex and variable. Tourmaline (and other mineralogy) veins may be from remobilized tourmaline laminae. Fold closures tend to be more heavily mineralized. Large tuff lapilli at 231'.

Unique DDH#: 12626 DDH#: 107 P295 File #: DH2951-082

Comments: Core largely broken. Upper 100' with much recrystallization. Hematite-goethite largely from weathering?. Trace disseminated pyrite in unweathered magnetite-silicate BIF.

Unique DDH#: 10007 DDH#: BM-11 P295 File #: DH2951-083

Comments: Most sulfides are stratiform. Interval 192-242' is deformed and hydrothermally altered. It offers a good example of goethite being a hydrothermal alteration product (in this case associated with sulfides?).

Unique DDH#: 14380 DDH#: 18131 P295 File #: DH2951-084

Comments: Iron formation is predominantly magnetite and silicate with minor sulfides disseminated in lamina. Transition into unit below is difficult to discern. Unit is deformed, and is probably an intrusive although it could be a tuff also. Deformation and associated alteration increases downward from the base of the iron formation to the mylonite.

Unique DDH#: 15491 DDH#: S360 P295 File #: DH2951-085

Comments: Oxidized iron oxides over entire core may be due to surficial weathering, hydrothermal processes, or both. Rock is deformed, folded and brecciated; allowing easy movement of fluids. Some solution collapse breccia also occurs, especially in the upper portions.

Unique DDH#: 10013 DDH#: BM-3 P295 File #: DH2951-086

Comments: Upper "metagabbro" appears locally fragmental, with a slight chance that the rock is tuffaceous. Sulfide bearing iron formation and chemical sediments are locally associated with brecciation. Sulfide veins could be remobilized stratiform sulfides. There is also the association with goethite with remobilized sulfides and iridescent coatings perhaps analogous to Duluth Complex chloride compounds. Brecciation may be tectonic or hydrothermal in origin.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 14381 DDH#: 18133 P295 File #: DH2951-087

Comments: Coarser sediment is quartz rich with larger intraclasts such as hematitic iron formation. Sulfide appears stratiform (quartz grain matrix?) but could also have been introduced. Sorting is generally poor, although core is strongly recrystallized. Phyllite may be ashy tuffs. Hematite alteration in the larger unit affects the phyllitic interbeds.

Unique DDH#: 10072 DDH#: 52 P295 File #: DH2951-088

Comments: Deformed and altered igneous rocks above and below the chemical sediments may be tuffaceous (especially below). Small amount of "lamprophyre" in the upper unit may or may not be related to the surrounding rock. Chemical sediment is typically laminated and contorted. Much if not all pyrite is secondary replacement of more primary pyrrhotite. Tan veinlets of siderite within 247-292' may be sphalerite, however if it is sphalerite, then it is low in iron content.

Unique DDH#: 10006 DDH#: G-9 P295 File #: DH2951-089

Comments: Laminated magnetite, silicate, sulfide chert iron formation and graphitic phyllite with minor quartz veining and sulfide veining toward base.

Unique DDH#: 14496 DDH#: AB-9 P295 File #: DH2951-090

Comments: Rock appears to relatively fresh metagabbro (amphibolite). Local fractures-shears with minor 1-2 mm mylonites (pseudotachylites?) and associated alteration occur locally. Disseminated sulfide is probably related to alteration based on spatial distribution.

Unique DDH#: 14660 DDH#: PA-4B-3 P295 File #: DH2951-091

Comments: Rock may have had basaltic or gabbroic parentage (or more mafic?). Veinlets with pink K-feldspar may or may not be related to hairline fractures with chlorite-clays. Core appears unmineralized.

Unique DDH#: 15492 DDH#: G-3 P295 File #: DH2951-092

Comments: Quartz-calcite alteration occurs throughout, and veins have a higher percentage of quartz. Disseminated pyrite may be part of the alteration or it may be more primary. The veins lack sulfides.

Unique DDH#: 15493 DDH#: G-2 P295 File #: DH2951-093

Comments: Schistose rock may not all be tuffaceous, although interval with chemical sediment has recognizable coarse clasts. Some dark cherty layers may be tourmalinites(?), although they are poorly crystalline. There is also some doubt about the original volcanic composition also.

Unique DDH#: 15494 DDH#: 61 P295 File #: DH2951-094

Comments: Tourmaline is found in the uppermost chemical sediment unit. Contact with adjacent rock is carbonatized. Basal rock unit is very dark, probably due to oxides, but could also be tourmaline related(?).

Unique DDH#: 10037 DDH#: 16 P295 File #: DH2951-095

Comments: Typical sulfide-graphite-chert (tuffaceous?) chemical sediments with magnetite, chlorite and tourmaline(?) toward base. Base of chemical sediments is believed to be black schist chlorite alteration (223'-233'). Basal contact (233') may be faulted. Footwall rock is locally sheared with an uncertain composition (felsic to mafic?). Footwall is extensively altered, especially with calcite. Disseminated sulfides may be alteration related (some look like visible gold?). Pillows may be present toward the base. Crystalline siderite looks like low Fe sphalerite (will assay).

Unique DDH#: 10002 DDH#: G-4 P295 File #: DH2951-096

Comments: Typical graphitic pyrrhotite chemical sediments with secondary pyrite and lesser amounts of other chemical sediments. Core has been heavily sampled with a quarter core left.

Unique DDH#: 10020 DDH#: G-1 P295 File #: DH2951-097

Comments: Typical graphitic pyrrhotite chert carbonate chemical sediment with secondary pyrite and veins with siderite, pyrite, and quartz.

Unique DDH#: 10063 DDH#: 43 P295 File #: DH2951-098

Comments: Typical graphite pyrrhotite chemical sediments with minor chert and carbonate; and increasing magnetite downward. Basal unit may be altered cherty tuff. Minor chalcopyrite coloration occurs locally.

Unique DDH#: 10008 DDH#: BM-12 P295 File #: DH2951-099

Comments: Upper tuff-chert (and portions of the lower unit) is very calcareous except where leached. "Clastic" texture and alteration could result from tectonic brecciation. Magnetite increases with depth.

Unique DDH#: 10011 DDH#: BM-10 P295 File #: DH2951-100

Comments: Substantial quartz veining locally in basal unit. Some sulfide may be Fe rich sphalerite. Bornite coloration is minor. Area around 133' is probably heavily altered footwall. Brecciation in core is probably hydrothermal in part. Chemical sediment-sulfide iron formation portion has been heavily sampled (1/4 core left) although no sample cards are present.

Unique DDH#: 10023 DDH#: 85 P295 File #: DH2951-101

Comments: Rock is largely a recrystallized to schistose calcareous chlorite, hornblende, quartz, grey hematite rock that is probably a tuffaceous chemical sediment or iron formation. Calcite may be due to alteration or may be more primary. Minor sulfides and graphite is also chemical sediment although some sulfide may be alteration associated. Locally there is appreciable quartz and calcite veining. More sulfides (and previous sampling) occurs in the core within the small tin boxes.

Unique DDH#: 10078 DDH#: 58 P295 File #: DH2951-102

Comments: The rock above and below the chemical sediments are relatively similar. Alteration and recrystallization has made their characterization difficult. Both may represent the stratigraphic footwall (repetition due to folding?). The upper one may have the more pronounced footwall associated alteration. The chemical sediment within 171-140' may be locally hydrothermally brecciated.

Unique DDH#: 10010 DDH#: BM-1 P295 File #: DH2951-103

Comments: Generally a phyllite to silicate iron formation with lesser oxide and sulfide, and is generally well laminated. Oxides predominate over sulfides in the basal unit. Heavily sampled except below 170'. Current sampling should catch the transition of sulfide to oxide better than previous sampling.

Unique DDH#: 10096 DDH#: 86 P295 File #: DH2951-104

Comments: Metabasalt or metagabbro becomes more sulfide bearing toward contact with chemical sediments, and is locally leached. Previously sampled by TLL (A16783). Other core from this hole may have more remaining chemical sediments.

Unique DDH#: 10016 DDH#: BM-6 P295 File #: DH2951-105

Comments: Contact of upper two units is sheared, with the uppermost unit very altered. Parent rock may have been tuff or altered metagabbro or metabasalt. Graphitic-sulfide units are typical. Sample interval contains carbonate and chert laminae within graphitic sulfides. Core otherwise relatively heavily sampled.

Unique DDH#: 15495 DDH#: N-1 P295 File #: DH2951-106

Comments: Core is apparently arenite and tuffaceous siltstones (phyllitic schist) with a minor recrystallized magnetite chem sediment contribution.

Unique DDH#: 15496 DDH#: N-3 P295 File #: DH2951-107

Comments: Similar to tuffaceous phyllite of N-1 except for scattered chert beds and a lack of magnetite.

Unique DDH#: 15497 DDH#: N-2 P295 File #: DH2951-108

Comments: Calcareous gabbro with quartz and calcite veins. Contains enough disseminated magnetite and pyrrhotite to be somewhat magnetic. Most silicates don't appear to be too altered.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 15498 DDH#: 84 P295 File #: DH2951-109

Comments: Sampled(?) by Lawler earlier but not assayed(?). Basal silicate chert sulfide carbonate oxide iron formation, chemical sediment or altered rock at base is massive to poorly laminated and siliceous. Overlying graphite and sulfide is finely laminated and contorted. Core could be sinter locally.

Unique DDH#: 15499 DDH#: 83 P295 File #: DH2951-110

Comments: Upper portion of core is extensively altered (calcite, sericite, quartz and vuggy). Textural hints indicate that the rock was probably fragmental and tuffaceous(?).

Unique DDH#: 10251 DDH#: S129 P295 File #: DH2951-111

Comments: Red hematitic-goethitic rock with local chert and/or rexlized quartz veins. Rock is more argillaceous-phyllitic toward the base.

Unique DDH#: 14382 DDH#: 18134 P295 File #: DH2951-112

Comments: Most pyrite is oxidized to limonite. Basal unit is altered and sheared, but textures look like metabasalt(?).

Unique DDH#: 14383 DDH#: 18137 P295 File #: DH2951-113

Comments: Footwall metabasalt is sheared and altered (decreasing downward?) with carbonate and sericite. Disseminated sulfide may also have resulted from alteration.

Unique DDH#: 14379 DDH#: 18129 P295 File #: DH2951-114

Comments: Silicate magnetite carbonate iron formation becomes more magnetite rich with depth. Most of sulfide is vein related.

Unique DDH#: 10121 DDH#: DL-1 P295 File #: DH2951-115

Comments: Fragmental rock may be a mylonite, but it definitely has the appearance of a "tuff" including flattened "fragments", and "quartz eyes". There is enough magnetite crystals to be somewhat magnetic. If a mylonite, parent rock was siliceous-feldspathic.

Unique DDH#: 10122 DDH#: DL-2 P295 File #: DH2951-116

Comments: May be a less(?) mylonitized parent rock for DL-1. Rock could be a mylonitized granite or siliceous-feldspathic sediment. Thin sections would help and perhaps analyses.

Unique DDH#: 10118 DDH#: DL-3 P295 File #: DH2951-117

Comments: Phyllitic to mylonitic rocks probably of tuff, chemical sediment (oxide), and clastic sediment parentage. Oxide chemical sediment is marked by secondary magnetite and minor red hematite. Mylonitization PROBABLY isn't able to create the fragmental textures present.

Unique DDH#: 10119 DDH#: DL-4 P295 File #: DH2951-118

Comments: Rock appears more "mafic" than other DL cores. It is probably felsic-intermediate tuff with a silicate-oxide-sulfide(?) chemical, sediment contribution, although the mylonitization could also be responsible for some textures. Toward the bottom especially, there are slightly coarser fragments reminiscent of gabbro, and perhaps this core is a mylonitized gabbro. Sulfide is disseminated pyrite especially noticeable within 55-65'.

Unique DDH#: 10120 DDH#: DL-5 P295 File #: DH2951-119

Comments: Rock is probably altered mafic metavolcanic, and is relatively altered down to 100' or so. Metabasalt appears to be largely actinolite (more magnesic than hornblende?) with iron in the form of magnetite, making the core somewhat magnetic. Local quartz or calcite blebs may have been amygdales. Minor disseminated pyrite occurs locally.

Unique DDH#: 15501 DDH#: 236 P295 File #: DH2951-120

Comments: Goethitic BIF w/ minor red hematite, and chert and silicate (tuff?) laminae. Silicate chemical sediment is chlorite (now clays?), and is located near the top. Toward base are disturbed chert laminae.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10318 DDH#: S238 P295 File #: DH2951-121

Comments: Hematite chert iron formation with disrupted chert and veins of hematite. Most deformation relatively brittle.

Unique DDH#: 10302 DDH#: 240 P295 File #: DH2951-122

Comments: Altered metabasalt. Alteration of ferromagnesians to chlorite and amphibole (calcareous also). Disseminated magnetite.

Unique DDH#: 10218 DDH#: S138 P295 File #: DH2951-123

Comments: Goethite (weathering product?) chert over laminated, slightly magnetic mag-chert silicate-carbonate iron formation. This may be tuffaceous, with mineralogy of silicates and carbonates (probably all siderite?) in question. Minor disseminated sulfide(?) occurs in some veins (with recrystallized quartz).

Unique DDH#: 10291 DDH#: S30 P295 File #: DH2951-124

Comments: The interval 120-135' may be hydrothermally altered in part with associated goethite, siderite(?), white quartz, and vugs. Mineralogy of tan, laminated "siderite" is uncertain.

Unique DDH#: 10268 DDH#: S45 P295 File #: DH2951-125

Comments: Rock is grey-hematite chert with considerable goethite in the upper portion. Recovery was poor. Grey hematite and goethite appear to replace chert(?).

Unique DDH#: 10347 DDH#: S46 P295 File #: DH2951-126

Comments: Laminated oxide-chert iron formation. Chert is leached(?) and could possibly be clastic or tuffaceous. Uppermost portion has secondary magnetite. Basal 60' is brecciated-mylonitized with associated replacement of chert by hematite.

Unique DDH#: 10269 DDH#: S47 P295 File #: DH2951-127

Comments: Little core left. Rock is fragmental chert (heavily replaced by grey hematite, or brecciated) in grey hematite matrix.

Unique DDH#: 10348 DDH#: 48 P295 File #: DH2951-128

Comments: Core is largely magnetite-silicate iron formation with minor quartz-carbonate?-sulfide veining and alteration. Contact with basal phyllite is red hematitic-goethitic (hydrothermal? alteration).

Unique DDH#: 10293 DDH#: S49 P295 File #: DH2951-129

Comments: Greenish chloritic iron silicates may be chemical sediment or mafic(?) tuff. This is primarily in the upper portion of the core, and with chert, appears to have been undergoing replacement by goethite and/or hematite.

Unique DDH#: 10213 DDH#: S50 P295 File #: DH2951-130

Comments: Laminated chert-oxide iron formation that is perhaps more goethitic and magnetic toward the top; and more grey hematitic toward the base. Several quartz veins with minor goethite and local vugs occur scattered.

Unique DDH#: 14497 DDH#: AB-28 P295 File #: DH2951-131

Comments: Good "greenstone" metavolcanics with minor disseminated pyrite, and minor quartz-pyrite veinlets, with sericite-muscovite especially along some slip surfaces.

Unique DDH#: 14500 DDH#: AB-27 P295 File #: DH2951-132

Comments: Graphitic argillite-phyllite that is brittley fractured (conjugate sets?) and quartz-pyrite veined (pseudobrecciated to brecciated). Probably some pyrrhotite is evenly dispersed within sediment. See MGS analyses; veined areas had higher Cu, Ag, Au, As, Sb, Hg, Mo, Pb and Zn.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10397 DDH#: S204 P295 File #: DH2951-133

Comments: Oxide chert iron formation; more goethitic toward top and red hematitic downward. More quartz veining downward(?).

Unique DDH#: 10172 DDH#: 206 P295 File #: DH2951-134

Comments: Similar to S204, except for greenish argillaceous portions. This may be tuffaceous. Schistosity cuts bedding at high angle which may indicate proximity to fold closure.

Unique DDH#: 10398 DDH#: 207 P295 File #: DH2951-135

Comments: Little core left. Upper cherty material is recrystallized, vuggy, and could be vein material. Lower portion is relatively soft, dolomitic-clayey(?) with hematite replacement.

Unique DDH#: 15503 DDH#: S208 P295 File #: DH2951-136

Comments: Deformed chert with lesser limonitic iron formation, graphitic sulfide iron formation, and chlorite-magnetite rock. Chlorite?-magnetite-goethite? may be hydrothermal alteration (black schist affiliated??) and is within 252-260'. Magnetite is secondary. Limonitic iron formation is largely within 265-277'. Some chert is very dark (from graphite-sulfides or tourmalinates?). Sulfide veining may be simple remobilization. Rock is deformed-sheared. Remnants in chert may be from tuff phenocrysts(?).

Unique DDH#: 10173 DDH#: 210 P295 File #: DH2951-137

Comments: Rock is deformed to brecciated. Phyllite is mostly in the upper 10', and has been locally replaced by iron (predominantly red hematite).

Unique DDH#: 10399 DDH#: S211 P295 File #: DH2951-138

Comments: Rock is vuggy to "sinter-like" except for the quartz veins which are fractured with minor goethite.

Unique DDH#: 10174 DDH#: 215 P295 File #: DH2951-139

Comments: Predominantly goethitic and magnetite (secondary?). Supergene?

Unique DDH#: 10300 DDH#: S225 P295 File #: DH2951-140

Comments: Somewhat phyllitic hematitic siltstone-argillite with quartz vein(?) fragments (brecciated). Little core left.

Unique DDH#: 10314 DDH#: S228 P295 File #: DH2951-141

Comments: Dark grey to red phyllite with variable iron content. Iron may be depositional or replacement. May contain local tuffaceous component(?).

Unique DDH#: 10315 DDH#: S232 P295 File #: DH2951-142

Comments: Laminated oxide chert iron formation. Magnetite is probably secondary. Little core left.

Unique DDH#: 10175 DDH#: 234 P295 File #: DH2951-143

Comments: Laminated chert silicate magnetite iron formation with local massive goethite. Schistosity may indicate proximity to fold hinge. May be tuffaceous. Magnetite is stratiform, but possibly secondary(?).

Unique DDH#: 10176 DDH#: S241 P295 File #: DH2951-144

Comments: Laminated magnetite-silicate iron formation with some goethite. Siliceous portions may be tuffaceous. Minor veins with quartz, chlorite, carbonate(?), and pyrite.

Unique DDH#: 10177 DDH#: S242 P295 File #: DH2951-145

Comments: Laminated magnetite-carbonate-silicate iron formation. Portions may be tuffaceous. Minor veins with quartz, chlorite, carbonate (dolomite?), and pyrite.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10320 DDH#: S244 P295 File #: DH2951-146

Comments: Laminated chert-goethite-red hematite iron formation with scattered late goethite-carbonate-quartz veinlets.

Unique DDH#: 10123 DDH#: S246 P295 File #: DH2951-147

Comments: Laminated oxide chert iron formation with minor quartz, goethite, carbonate veining.

Unique DDH#: 10303 DDH#: 247 P295 File #: DH2951-148

Comments: Laminated chert-oxide iron formation over greenish altered rock (largely clay, chlorite, sheet silicates, epidote; with fragments of red hematite and limonite). Altered rock appears brecciated with unknown parentage (mafic? metavolcanic?).

Unique DDH#: 10321 DDH#: S248 P295 File #: DH2951-149

Comments: Laminated chert oxide silicate iron formation. Iron silicates appear to be chloritic, although hematite (alteration?) makes textures difficult to discern. This could be chemical sediment, tuffaceous material or alteration products. Also, other portions of core may be silty clastic rocks and not cherty also.

Unique DDH#: 10178 DDH#: S250 P295 File #: DH2951-150

Comments: Phyllite contains no graphite. Minor disseminated sulfide is stratiform(?), perhaps associated with thin tuffaceous laminae. Red hematite may be secondary replacement. Good phyllite, with a local development of linear fabric (associated with fold closures or shears?).

Unique DDH#: 10322 DDH#: S251 P295 File #: DH2951-151

Comments: Laminated chert oxide silicate iron formation, generally subparallel to core axis with gentle fold closures. Silicates (chlorites?) may be tuff associated(?). Core is slightly magnetic from magnetite.

Unique DDH#: 10323 DDH#: S254 P295 File #: DH2951-152

Comments: Laminated chert oxide silicate iron formation, generally subparallel to core axis. Silicates (chlorites?) may be tuff associated(?), although textures are not discernible due to iron oxides. Core is very slightly magnetic from magnetite.

Unique DDH#: 10179 DDH#: S256 P295 File #: DH2951-153

Comments: Iron formation over phyllite. Goethite-magnetite-grey hematite iron formation results from secondary processes (hydrothermal or surficial weathering focussed along fractures). This unit contains vugs with drusy quartz(?). Basal phyllite is sericitic (almost "talcy" locally), and is locally hematitic.

Unique DDH#: 10301 DDH#: S257 P295 File #: DH2951-154

Comments: Altered-retrograde metamorphosed gabbro with minor disseminated sulfides. Probably hypabyssal. Trace of hematite staining along some fractures.

Unique DDH#: 10180 DDH#: 260 P295 File #: DH2951-155

Comments: Rock within 103-107' is a breccia (fault) of quartz and interstitial iron oxides. Some late iron oxide alteration appears locally, but brecciation did not appear to have effected the mineralogy of the pre-brecciation oxides.

Unique DDH#: 10325 DDH#: S261 P295 File #: DH2951-156

Comments: Textures are difficult to identify due to iron oxides, however it does appear to be schistose or somewhat phyllitic, with iron silicates (chlorite) or perhaps mafic volcanics(?). Rock is slightly magnetic.

Unique DDH#: 10326 DDH#: S264 P295 File #: DH2951-157

Comments: Laminated chert red hematite iron formation. High angle strain slip cleavage to bedding indicates possible proximity to fold axis. Local remobilization.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10181 DDH#: 265 P295 File #: DH2951-158

Comments: Alternating magnetite-silicate (tuffaceous?) laminated iron formation, with minor veins with quartz, pyrite, magnetite?, grey hematite, and chlorite or other iron silicates. Magnetite may have minor disseminated pyrite (stratiform).

Unique DDH#: 10327 DDH#: S268 P295 File #: DH2951-159

Comments: Little core left. Rock may have iron silicate or carbonate component in the iron formation. Some goethitic-limonitic alteration around disrupted chert laminae.

Unique DDH#: 10182 DDH#: 270 P295 File #: DH2951-160

Comments: Remaining core is vein quartz with carbonate (dolomite-siderite?), goethite, and grey hematite. Local vugs occur with grey hematite needles. No country rock recognizable.

Unique DDH#: 10233 DDH#: S271 P295 File #: DH2951-161

Comments: Little core left. Rock is oxide chert iron formation and phyllitic(?) siltstone. Rock is deformed.

Unique DDH#: 10329 DDH#: S274 P295 File #: DH2951-162

Comments: Goethite magnetite grey hematite iron formation. Little core left. Upper materials (not mentioned in sumlog) appear to be glacial gravel-cobbles of granite and tonalite.

Unique DDH#: 10234 DDH#: S275 P295 File #: DH2951-163

Comments: Chert oxide iron formation, locally fairly magnetic. Laminae are deformed.

Unique DDH#: 10124 DDH#: 276 P295 File #: DH2951-164

Comments: Laminated magnetite-silicate iron formation with minor chert. Some silicate portions may be sideritic. Some silicates may be goethitic colored. Separate goethite grains may be oxidized sulfides. Rock is folded with possible interferences patterns.

Unique DDH#: 10331 DDH#: S279 P295 File #: DH2951-165

Comments: Laminated red hematite chert iron formation. Pyrite "trapped" or isolated in chert may indicate that pyrite was the precursor to the red hematite (oxidized).

Unique DDH#: 10183 DDH#: 281 P295 File #: DH2951-166

Comments: Interbedded contact of iron formation with grey phyllite, with heavy replacement of phyllite by red hematite near the contact.

Unique DDH#: 10190 DDH#: S15 P295 File #: DH2951-167

Comments: Laminated magnetite, silicate, carbonate iron formation. Local carbonate goethite quartz alteration veins. No visible sulfides.

Unique DDH#: 10184 DDH#: S295 P295 File #: DH2951-168

Comments: Chert oxide silicate iron formation, with magnetite, goethite, red and grey hematite(?). Rock has minor vugs locally throughout. Carbonate(?) may be more dolomitic than anything.

Unique DDH#: 10336 DDH#: S296 P295 File #: DH2951-169

Comments: Laminated magnetite silicate and chert(?) iron formation. Could be stratiform quartz vein instead of recrystallized chert. Core may have siderite also.

Unique DDH#: 10345 DDH#: 292 P295 File #: DH2951-170

Comments: Laminated silicate magnetite iron formation, with surface weathering oxidation to hematite in upper portion. Contains minor stratiform sulfide and siderite locally. Quartz vein at 134-135' has goethite red hematite at lower contact. Quartz vein at 143' contains sulfides.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10379 DDH#: S118 P295 File #: DH2951-171

Comments: Brecciated hematite chert iron formation(?) with chlorite and other silicates. Much fine-grained secondary recrystallization of red hematite, silicates, and possibly carbonate. Fault brecciation(?). Alteration could be hydrothermal or from surficial weathering.

Unique DDH#: 10380 DDH#: 121 P295 File #: DH2951-172

Comments: Vuggy chert and oxide iron formation. Could be hydrothermal alteration or from surficial weathering.

Unique DDH#: 10381 DDH#: S127 P295 File #: DH2951-173

Comments: Vuggy chert and oxide iron formation. Could be hydrothermal alteration or from surficial weathering.

Unique DDH#: 10382 DDH#: S128 P295 File #: DH2951-174

Comments: Vuggy chert and oxide iron formation. Could be hydrothermal or from surficial weathering. Basal quartz vein, besides hematite, contains medium grained muscovite near margins. Analysis of vein interval will be cuttings with portions of the vein core since there is little core. Whether any of this vein material was crushed in this cuttings interval is unknown. Compare with unique DDH S118.

Unique DDH#: 10253 DDH#: S316 P295 File #: DH2951-175

Comments: Little core. Composed of sericitic phyllite (with ghosts of tuffaceous fragments?) and siliceous siltstone, arenite or chert. This appears to be clastic and is probably silicified. Minor red and grey hematite laminae-veins occur locally. Use ratios when comparing chemistry with other phyllites because of silica addition.

Unique DDH#: 10254 DDH#: S317 P295 File #: DH2951-176

Comments: Oxide chert iron formation. More goethitic toward base. Minor quartz hematite veins and also minor carbonate quartz goethite veinlets.

Unique DDH#: 10255 DDH#: S318 P295 File #: DH2951-177

Comments: Oxide chert iron formation with minor quartz goethite (and carbonate?) veinlets.

Unique DDH#: 10217 DDH#: S324 P295 File #: DH2951-178

Comments: Oxide iron formation with minor chert. Chert may also be siliceous tuff or some other exhalative. Mineralogy may be more than quartz.

Unique DDH#: 10257 DDH#: S325 P295 File #: DH2951-179

Comments: Chert oxide silicate iron formation with fracturing and veining toward the base with pyrite, quartz, and grey hematite.

Unique DDH#: 10258 DDH#: S326 P295 File #: DH2951-180

Comments: Goethite chert iron formation over tuffaceous(?) phyllite that is partially altered to red hematite.

Unique DDH#: 10259 DDH#: S327 P295 File #: DH2951-181

Comments: Chert oxide iron formation with minor calcite veining near top, and oxide veins towards base.

Unique DDH#: 10289 DDH#: S29 P295 File #: DH2951-182

Comments: Oxide chert argillaceous iron formation over the same with chloritic-carbonate phyllite (with porphyroblastic siderite). Phyllite and chert is locally pyritic (stratiform?) and may indicate that sulfides were more common before iron oxidation. Basal phyllite is very dark and may be graphitic; and is locally siliceous. This could be an alteration product and not a clastic-chemical sediment.

Unique DDH#: 10210 DDH#: S33 P295 File #: DH2951-183

Comments: Goethite chert grey hematite iron formation with minor silicate iron formation or argillite (tuffaceous?). Local calcite veinlets occur locally.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10359 DDH#: S31 P295 File #: DH2951-184

Comments: Red to grey slightly phyllitic argillite that is probably carbonate (dolomite?) bearing. Red hematitic alteration is sporadic. Calcite veinlets occur locally.

Unique DDH#: 15504 DDH#: S330 P295 File #: DH2951-185

Comments: Goethitic iron formation with brittle fractures-brecciation, calcite and pyrite veins. Little core, but cuttings for 92-235' can be analyzed.

Unique DDH#: 10361 DDH#: S36 P295 File #: DH2951-186

Comments: Oxide (with minor chert) iron formation over argillite. Magnetite is present in upper part of oxide iron formation. Brecciation, and oxidation increases downward, and is most prevalent in 200-220'. Calcite quartz veining is also associated with the predominant goethite alteration of oxides. Brecciation also occurs at contact with argillite, where variable red hematite alteration occurs. Hydrothermal? or surficial alteration along shears(?)

Unique DDH#: 10211 DDH#: S37 P295 File #: DH2951-187

Comments: Core is phyllite that is locally dolomitic(?) and calcareous. Rock appears to be sericitic.

Unique DDH#: 10264 DDH#: S38 P295 File #: DH2951-188

Comments: Argillaceous (now micas?) red hematite-goethite iron formation. Unit more goethitic toward base. Quartz veins contain minor calcite, and also hematite fragments.

Unique DDH#: 10265 DDH#: S39 P295 File #: DH2951-189

Comments: Sericitic phyllite and chert. Chert could also be silicified phyllite. Local red hematite staining, especially associated with replacement of (pyrite?) cubes by red hematite.

Unique DDH#: 10185 DDH#: S40 P295 File #: DH2951-190

Comments: Oxide iron formation over hematitic phyllite. Local quartz veining (with brecciation?, minor pyrite), especially near top. Clayey silicate(?) iron formation at 135-140'. Minor oxidation and vugs occur locally. Hematite in phyllite may be alteration.

Unique DDH#: 10266 DDH#: S41 P295 File #: DH2951-191

Comments: Predominantly grey hematite oxide chert iron formation. Minor quartz oxide veining with some calcite toward base. Vein pyrite may be stratiform-related to silicate portion of iron formation. Little core left, with no core between 160 and 218'.

Unique DDH#: 10267 DDH#: S42 P295 File #: DH2951-192

Comments: Similar to DDH S41 (unique 10266) lithologically. Sulfide and silicate portions appear to be more stratiform than cross-cutting (chemical sediment or stratiform alteration?).

Unique DDH#: 10195 DDH#: S5 P295 File #: DH2951-193

Comments: Oxide chert iron formation with carbonate goethite quartz red hematite alteration. Rock is locally vuggy with drusy carbonate or barite.

Unique DDH#: 10294 DDH#: S6 P295 File #: DH2951-194

Comments: Goethite grey hematite chert silicate iron formation with phyllite locally within 135-140'. Phyllite has dark grains of organic matter, phosphate or iron oxides. Core locally limonitic and slightly calcareous.

Unique DDH#: 10196 DDH#: S7 P295 File #: DH2951-195

Comments: Laminated goethite grey hematite silicate iron formation, with veining reactivating these components.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10346 DDH#: S43 P295 File #: DH2951-196

Comments: Iron formation over phyllite. Basal iron formation and phyllite are fragmental (faulting-brecciation). Fragments phyllite are rounded (abraded during brecciation?), with fragments appearing to predate foliation formation (need thin section). Disseminated-blebby pyrite may be stratiform or remobilized (some oxidized to red hematite). Minor amount of very fine grey hematite(?) in some laminae.

Unique DDH#: 11444 DDH#: BM-2 P295 File #: DH2951-197

Comments: Brecciated to mylonitic argillitic red hematite, chert, magnetite, silicate(?) iron formation over phyllite. Silicification and quartz veins common in iron formation, with lesser calcite and local pyrite in quartz veins. Local fractured fold closures present.

Unique DDH#: 15505 DDH#: 101 P295 File #: DH2951-198

Comments: More cuttings than core. Material with sulfides(?) had more corroded tin boxes, especially the intervals 185-195' and 240-250' (possible contamination in analytical samples?). Corrosion was less extreme in the other tins. Altered basalt or andesite may be altered from weathering or retrograde metamorphism. Presumed not to be Keweenawan. This sample for analysis is core and no cuttings. Sample of graphite sulfide phyllite only cuttings-core fragments. Basal silicate goethite iron formation mineralogy uncertain. Color of cuttings are 5 Y 4/4 (125-135'), 10 YR 4/2 (135-140'), 5 GY 5/1 (140-150'), 10 YR 5/2 (150-160'), 5 YR 3/1 (185-195'), 10 YR 3/2 (240-250'), 10 YR 4/2 (260-270'), and 10 YR 3/2 (270-275').

Unique DDH#: 15506 DDH#: 102 P295 File #: DH2951-199

Comments: Cuttings in 190-200', 210-220' and 320-327' were in heavily corroded tin boxes (from sulfides?). Other tins were less corroded. The tuffaceous greywacke may be andesitic to dacitic. This gets calcareous toward the base where the rock has round calcite quartz cavity fillings (look like amygdales). Cuttings colors are 10 YR 6/4 (152-160'), 10 YR 6/6 (160-170'), 10 R 4/4 (180-190'), 5 YR 6/4 (190-200'), 10 YR 6/4 (210-220'), 10 YR 6/2 (250-260'), and 10 YR 6/4 (260-270').

Unique DDH#: 15507 DDH#: 103 P295 File #: DH2951-200

Comments: Core amount increases downward. Uppermost phyllite (124-128') appears to contain a fair amount of goethite and magnetite in the cuttings. Color of cuttings are 5 YR 3/2 (124-128'), 5 YR 3/4 (140-143'), 5 YR 3/2 (150-155'), 5 YR 3/4 (155-160'), and 5 Y 3/1 (160-170'). Original tin boxes showed only minor to moderate corrosion.

Unique DDH#: 15508 DDH#: 104 P295 File #: DH2951-201

Comments: Very little core. Cuttings appear to have increased goethite magnetite below 209'. The interval 275-280' appears to have some sulfate oxidation (from sulfides?), with the original tin box very corroded (geochem sample contaminated?). Color of cuttings are 10 YR 6/4 (175-209'), 10 YR 4/2 (209-230'), 5 YR 4/4 (250-265'), 10 YR 5/4 (265-270'), 5 YR 4/4 (270-275'), and 5 YR 3/2 (275-280').

Unique DDH#: 10290 DDH#: S3 P295 File #: DH2951-202

Comments: Hematite goethite chert iron formation with minor thin quartz pyrite veins.

Unique DDH#: 10292 DDH#: S4 P295 File #: DH2951-203

Comments: Silicate (and carbonate?) chert with relatively minor magnetite iron formation, over goethite chert red hematite limonite iron formation. Minor quartz pyrite veins in upper material. Minor pyrite gash fillings occur in brittle boudinaged chert laminae. Basal portion may have pyrite veins(?).

Unique DDH#: 10295 DDH#: S8 P295 File #: DH2951-204

Comments: Chert red hematite predominating iron formation over goethite predominating iron formation. Goethite appears to be replacing-cross cutting the red hematite (and chert?). Chert red hematite portions contain minor quartz pyrite veins.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10197 DDH#: S9 P295 File #: DH2951-205

Comments: Predominantly chert oxide iron formation that appears to be brecciated locally. Minor pyrite(?) may occur as veins, along with iron silicate or carbonate. Basal portion is argillitic.

Unique DDH#: 10275 DDH#: S10 P295 File #: DH2951-206

Comments: Greenish chert silicate (and carbonate?) iron formation with goethite (and more localized hematite quartz) alteration toward the top.

Unique DDH#: 10278 DDH#: S11 P295 File #: DH2951-207

Comments: Predominantly goethite with minor chert and limonite.

Unique DDH#: 10188 DDH#: S12 P295 File #: DH2951-208

Comments: Magnetite silicate carbonate(?) iron formation with some chert and minor veining. Possible some disseminated stratiform sulfides. Some quartz veins have a trace of green coloration (mineral? such as chlorite? or fuchsite??).

Unique DDH#: 10282 DDH#: S13 P295 File #: DH2951-209

Comments: Goethite chert iron formation with minor hematite (alteration of goethite). Local cross cutting vuggy silica or silicate(?).

Unique DDH#: 10189 DDH#: S14 P295 File #: DH2951-210

Comments: Rock is locally vuggy and sintery in appearance. Chert is dark grey (graphitic?) in the upper portion, with disseminated to blebby pyrite (part of chert chemical sediment or later alteration product?). At lower contact with limonitic goethitic clayey rock is siderite or sphalerite veins-alteration with sheet silicates(?). Local vugs in basal grey hematite chert iron formation has goethite and minor chlorite(?) and perhaps carbonate(?).

Unique DDH#: 10202 DDH#: S21 P295 File #: DH2951-211

Comments: Chert hematite iron formation over phyllite. Brecciation and local veining in iron formation. Phyllitic texture variably developed, and rock appears fragmental (probably fault breccia, not tuff?). Argillaceous rock is variably replaced by red hematite (paint rock), especially near contact with overlying iron formation. Chert has oxide remnants of cubes locally (after pyrite?).

Unique DDH#: 10192 DDH#: S22 P295 File #: DH2951-212

Comments: Magnetite chert silicate iron formation with local minor goethitic alteration and quartz or grey hematite veins. Silicate carbonate portions may have minor pyrite.

Unique DDH#: 10288 DDH#: S20 P295 File #: DH2951-213

Comments: Largely altered argillaceous rock and lesser chert red hematite iron formation. Argillaceous rock-phyllite is limonitic to goethitic to red hematitic, and is generally clayey. Textures indicate ductile deformation of "phyllite" and more brittle deformation of chert. Iron alteration of argillaceous rock may be surficial or fault related(?). Minor pyrite veining is preserved near some chert.

Unique DDH#: 10204 DDH#: S23 P295 File #: DH2951-214

Comments: Laminated red hematite chert magnetite silicate (and carbonate?) iron formation. Green silicate portions could be argillaceous-tuffaceous. Magnetite is spotty (replaced by red hematite?). Breccia within 200-205'.

Unique DDH#: 10193 DDH#: S24 P295 File #: DH2951-215

Comments: Laminated magnetite silicate carbonate iron formation, perhaps with minor chert in some silicate laminae. Local recrystallization of magnetite and minor veinlets-fractures with quartz and goethite(?).

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10206 DDH#: S25 P295 File #: DH2951-216

Comments: Chert grey hematite iron formation over red and greenish phyllite, with chert and green tuffaceous (mafic?) material at the contact. Phyllite appears locally brecciated, and is variably altered-oxidized to red hematite. Greenish portions MAY contain very fine-grained pyrite(?). Some portions of phyllite appear to be goethitic (?). Chert locally contains iron oxide cubes (after pyrite?).

Unique DDH#: 10194 DDH#: S27 P295 File #: DH2951-217

Comments: Laminated magnetite iron formation with minor chert and silicates (and carbonate?), upper part of which contains much goethite. Below this is a thin brecciated phyllite (mylonitic?), below which magnetite is associated with grey hematite. A few thin red hematite goethite clay altered intervals occur within this lower portion (shear related?).

Unique DDH#: 12019 DDH#: MO-1 P295 File #: DH2951-218

Comments: Sand (assuming from sandstone) is generally poorly cemented except where quartz cement or pressure welding. Sand is typically tinted hematite pink to limonite yellow. Rock is probably Keweenawan rift fill or less likely Cambrian. Locally cemented in 1-2 mm blebs of goethite, other iron oxides, or pyrite. Interval 180-185' is very goethitic.

Unique DDH#: 12018 DDH#: MO-2 P295 File #: DH2951-219

Comments: Similar to MO-1 except no pyrite seen, and perhaps more grey hematite and magnetite (contamination? from above). Unit contains locally numerous round (concretionary?) goethite grains, especially within 175-280'. Sediment is probably Keweenawan rift fill or (less likely) Cambrian.

Unique DDH#: 12017 DDH#: MO-3 P295 File #: DH2951-220

Comments: Similar to other MO holes except sand has more recovered silt. Sand is predominantly with minor limonite. There appears to be much contamination from upper glacial materials down to perhaps 145' or so. Sandstone is probably Keweenawan rift fill or less likely Cambrian.

Unique DDH#: 12617 DDH#: R-1 P295 File #: DH2951-221

Comments: Hornblende, plagioclase, quartz, biotite, magnetite schist with local basalt or granite intrusives along shears. Basalts are less than 10' thick and granites are less than 1'. Granite is typically with quartz k-feldspar intergrowths. Alteration (also associated with at least some shears) is typically carbonatization. Disseminated magnetite occurs throughout making the unit somewhat to moderately magnetic. Disseminated sulfide occurs throughout but may be more alteration associated. Analyzed interval is veined and carbonatized in general. Basalt is probably Keweenawan.

Unique DDH#: 12750 DDH#: PR-1 P295 File #: DH2951-222

Comments: Generally ferruginous, probable Keweenawan rift fill sands, silts and sedimentary breccia-conglomerate over gneiss. Sedimentary breccia conglomerate increases with depth. Gneiss is locally sheared. Contact deformation of overlying sediment may be due to tectonism or deposition over an irregular surface or both. Minor disseminated pyrite (rare grains) occur throughout, but most common toward the contact with the gneiss. Much dolomite veining near contact with the gneiss.

Unique DDH#: 15502 DDH#: 201 P295 File #: DH2951-223

Comments: Log based on rock chips in cuttings. Magnetite goethite silicate iron formation over altered schistose metagabbro. Lower rock is clayey and appears to be sheared (and contact sheared?). Glacial material is more clayey within 65-75'.

Unique DDH#: 10148 DDH#: S253 P295 File #: DH2951-224

Comments: Core in cuttings boxes. Laminated, somewhat phyllitic sulfide graphite iron formation. May possibly contain Mn oxides(?). Minor veinlets with red siderite (or sphalerite?).

Unique DDH#: 10263 DDH#: S130 P295 File #: DH2951-225

Comments: Laminated silicate carbonate iron formation with chert and magnetite. Locally cut by veins with calcite, quartz, and pyrite. Porphyroblastic(?) dark siderite or sphalerite occurs within 215-220'.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10383 DDH#: S131 P295 File #: DH2951-226

Comments: Oxide chert iron formation with minor quartz goethite calcite veins. Chert locally vuggy.

Unique DDH#: 10384 DDH#: S133 P295 File #: DH2951-227

Comments: Oxide chert iron formation with minor quartz goethite calcite veins. Hydrothermal alteration(?)

Unique DDH#: 10160 DDH#: S134 P295 File #: DH2951-228

Comments: Oxide chert iron formation with minor quartz goethite calcite veins. Large quartz vein at top has minor calcite and goethite.

Unique DDH#: 10219 DDH#: S140 P295 File #: DH2951-229

Comments: Carbonate silicate magnetite chert (sulfide?) iron formation, with minor carbonate pyrite goethite quartz veinlets. Some sulfide may be stratiform.

Unique DDH#: 10385 DDH#: S142 P295 File #: DH2951-230

Comments: Argillaceous hematite iron formation and ferruginous phyllite, with minor goethite.

Unique DDH#: 15500 DDH#: S143 P295 File #: DH2951-231

Comments: Typical oxide chert silicate iron formation, with minor fractures, veinlets, vugs and calcite.

Unique DDH#: 10220 DDH#: S144 P295 File #: DH2951-232

Comments: Oxide chert argillite (tuffaceous?) iron formation. Argillitic portion is locally very calcareous (presumed alteration?). Rock is folded to perhaps brecciated.

Unique DDH#: 10405 DDH#: S146 P295 File #: DH2951-233

Comments: Laminated chert oxide silicate (and carbonate?) iron formation with minor sulfide(?) that is probably stratiform(?)

Unique DDH#: 10222 DDH#: S148 P295 File #: DH2951-234

Comments: Chert magnetite silicate (and carbonate?) grey hematite goethite iron formation. Goethite portion (alteration) could be hydrothermal and/or surficial.

Unique DDH#: 10386 DDH#: S149 P295 File #: DH2951-235

Comments: Chert hematite iron formation with minor goethite and minor hairline veinlets with quartz and iron oxides.

Unique DDH#: 10387 DDH#: S150 P295 File #: DH2951-236

Comments: Chert hematite iron formation with minor hairline veinlets with quartz and iron oxides. Also local fractures with offset. Chert is locally vuggy.

Unique DDH#: 10388 DDH#: S151 P295 File #: DH2951-237

Comments: Chert hematite iron formation with minor hairline veinlets with quartz and iron oxides. Chert is locally vuggy or contains blebby hematite. Local layers with 1-2 mm muscovite (alteration? or tuffaceous component?).

Unique DDH#: 10223 DDH#: S152 P295 File #: DH2951-238

Comments: Hematite goethite magnetite chert iron formation, with minor oxide carbonate quartz alteration veinlets. Magnetite may be associated with goethite (alteration?).

Unique DDH#: 10389 DDH#: S154 P295 File #: DH2951-239

Comments: Red (and tan) hematitic phyllite with minor red hematite iron formation and chert. Rock is deformed with local brecciation of chert. Minor calcite quartz limonite along veinlets.

Unique DDH#: 10390 DDH#: S155 P295 File #: DH2951-240

Comments: Red hematite chert iron formation, with local quartz (minor calcite) veinlets and associated drusy quartz.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10161 DDH#: S156 P295 File #: DH2951-241

Comments: Red hematite chert goethite iron formation with local quartz veins with minor pyrite locally. Chert also has oxide replacing cubes (pyrite?), and is also locally vuggy.

Unique DDH#: 10162 DDH#: 158 P295 File #: DH2951-242

Comments: Argillaceous oxide iron formation with minor slickensides and hematite veinlets. Minor pyrite along some veinlets-shears.

Unique DDH#: 10163 DDH#: S160 P295 File #: DH2951-243

Comments: Argillaceous iron formation to hematitic phyllite. May contain scattered pyrite(?) or mica grains.

Unique DDH#: 10164 DDH#: 163 P295 File #: DH2951-244

Comments: Argillaceous iron formation to hematitic phyllite.

Unique DDH#: 10304 DDH#: S166 P295 File #: DH2951-245

Comments: Predominantly goethitic iron formation and quartz vein with minor goethite and calcite. Goethite has a sinistral texture, and may be hydrothermal alteration.

Unique DDH#: 10165 DDH#: 168 P295 File #: DH2951-246

Comments: Argillaceous goethite hematite magnetite silicate iron formation with local veinlets with magnetite or pyrite with quartz. Upper portion of core is more goethitic and magnetitic, with the basal 10' more hematitic.

Unique DDH#: 10166 DDH#: 172 P295 File #: DH2951-247

Comments: Oxide chert iron formation. Limonite goethite hematite may be from surficial weathering. Oxide replacing pyrite(?) cubes in chert locally.

Unique DDH#: 10391 DDH#: S173 P295 File #: DH2951-248

Comments: Oxide chert silicate(?) iron formation. Could also be argillaceous(?). Red hematite, goethite, limonite probably from surficial weathering. Color of crushed core is 10R 3/4 (103-108'), 10R 4/4 (108-113'), and 5YR 4/4 (113-133').

Unique DDH#: 10392 DDH#: 179 P295 File #: DH2951-249

Comments: Red hematitic phyllite with brecciated chert layers. Only core below 125'. Crushed core colors are 10R 5/6 (104-109', 125-130'), 10R 6/6 (109-114'), 10R 3/6 (114-120'), and 10R 4/6 (120-130').

Unique DDH#: 10167 DDH#: 182 P295 File #: DH2951-250

Comments: Magnetite chert silicate carbonate iron formation with minor veinlets with quartz, carbonate, and hematite or local limonite. Color of crushed core is 5YR 4/2 (92-93'), 5Y 3/1 (93-98'), 10YR 3/2 (98-108'), and 10YR 2/2 (108-113').

Unique DDH#: 10393 DDH#: S183 P295 File #: DH2951-251

Comments: Argillaceous chert red hematite silicate iron formation. Chert is broken-brecciated locally, and contains oxidized pyrite cubes (now hematite). Color of crushed core is 5R 3/2 (95-101'), 10R 2/4 (101-106'), and 10R 3/4 (106-111').

Unique DDH#: 10168 DDH#: 186 P295 File #: DH2951-252

Comments: Rock is largely vein quartz with minor goethite, calcite(?), and one pyrite grain along internal fractures. Remaining rock is predominantly goethite (local vugs), quartz, and calcite (minor), and is probably hydrothermal alteration products associated with the quartz vein.

Unique DDH#: 10394 DDH#: S187 P295 File #: DH2951-253

Comments: Locally vuggy oxide silicate carbonate iron formation that is extremely altered, and is predominantly red hematite, limonite and goethite. Dark porphyroblastic siderite(?) is locally common. Color of crushed core is 5R 3/6 (94-110'), and 10R 4/4 (110-115').

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10169 DDH#: 192 P295 File #: DH2951-254

Comments: Oxide chert iron formation with local tuffaceous or silicate portions with difficult textures. Core is locally deformed to mylonitic. Contains typical minor veinlets with quartz carbonate goethite and other iron oxides.

Unique DDH#: 10395 DDH#: 193 P295 File #: DH2951-255

Comments: Sheared clayey rock is probably tuffaceous (greenish colored), but could be partially argillaceous. Contains abundant quartz grains (quartz eyes??), possible feldspar phenocrysts, and other fragments; all of which could also be tectonic. Crushed core is colored 10YR 5/2 (98-103'), 10YR 6/4 (103-115'), and 10YR 4/4 (115-120').

Unique DDH#: 10170 DDH#: S195 P295 File #: DH2951-256

Comments: Oxide chert iron formation with minor silicate-carbonate iron formation. Oxide is goethite, grey hematite (some replacing other components?). Minor carbonate quartz veinlets occur locally.

Unique DDH#: 10396 DDH#: S201 P295 File #: DH2951-257

Comments: Vuggy fractured oxide chert iron formation. Very vuggy and fractured. Red hematite probably from surficial weathering, but other features may be related to tectonism and/or hydrothermal alteration(?).

Unique DDH#: 12752 DDH#: RS-2 P295 File #: DH2951-258

Comments: Probable Keweenawan rift sediment unconformably over gneiss. Sediment is either reddish (hematitic) or greenish (reduced Fe), with minor disseminated pyrite in greenish portions. Calcite cement becomes more dolomitic toward unconformity. Feldspar and quartz grains make up most of the coarser grains. Gneiss is sheared to schistose locally, and locally contains late fractures with minor pyrite.

Unique DDH#: 10133 DDH#: S331 P295 File #: DH2951-259

Comments: Only remaining material is crushed core or cuttings. Material appears to be largely quartz vein and goethitic to argillaceous material. A few recognizable fragments are fragmental with slickensides. Minor disseminated pyrite also occurs. Host rock of veins may not have had much iron. Color of the material is 5YR 6/4 (103-113'), 5YR 5/4 (113-133'), 10YR 6/4 (133-138'), 10YR 5/4 (138-143'), 10YR 6/4 (143-148'), and 5YR 5/6 (153-158').

Unique DDH#: 12618 DDH#: 265-1/1 P295 File #: DH2951-260

Comments: Rock is altered (to chlorite, clays, hornblende?) dark green mafic-ultramafic rock. Some grains appear to be olivine or pyroxene (originally), and generally are rounded. Company log reports calcite veins and dark mica.

Unique DDH#: 10511 DDH#: LS-10 P295 File #: DH2951-261

Comments: Rock is medium-grained granite, with reddish K-feldspar (hematite) and epidote alteration. Variable glacial contamination decreases with depth.

Unique DDH#: 10512 DDH#: LS-11 P295 File #: DH2951-262

Comments: Rock is medium-grained granite, with pinkish K-feldspar and variable alteration (especially of feldspar, albitization and clays). Very clayey in the upper portion of the samples (weathering presumed). Possible glacial contamination decreases with depth.

Unique DDH#: 12759 DDH#: DRP-1 P295 File #: DH2951-263

Comments: Core appears to be going up section through a metamorphosed volcaniclastic-sediment pile topped by chemical sediments. Below 170' or so, textures indicate a primary coarser fragmental nature (also less mafics with depth(?), and increasing(?) sulfide (minor however). Biotite in this sediment-volcaniclast schist has a peculiar dark grey color (possibly a dark grey chlorite?? instead of biotite). Chert marble chemical sediment is locally vuggy and sinterly looking, and is locally brecciated and recemented, generally with calcite (marble). Marble may contain minor tremolite(?). Basal dark clayey altered breccia probably is NOT the more mafic portion of the next sequence, as the K feldspar fragments in the basal 10' or so may indicate. Relatively minor sulfides in general, with the most in the graphitic portions. Relatively little carbonate outside the marble.

Unique DDH#: 12760 DDH#: DRP-2 P295 File #: DH2951-264

Comments: Similar to DRP-1. Upper schist unit like DRP-1 contains disrupted chert layers or quartz veins, and some of the "fragmental" nature may result from this. They are generally little quartz in the "marble" unit. Schist within marble may indicate that carbonate is perhaps a replacement. In general, upper schist is finer(?) grained than the same unit in DRP-1 (more distal??). This schist may contain more sulfide (pyrite-pyrrhotite) than in DRP-1. Marble in DRP-2 appears to be considerably thicker. Contact is more sheared.

Unique DDH#: 12758 DDH#: JW-1 P295 File #: DH2951-265

Comments: Schist probably derived from volcanic sediments or volcanics (intermediate? to locally mafic?). Hints of larger fragments, but if so, then they are extremely flattened. Minor calcite veins, especially in a more mafic portion at about 142'.

Unique DDH#: 12751 DDH#: RS-1 P295 File #: DH2951-266

Comments: Keweenawan sediment unconformably over gneiss. Not as much carbonate as in contact as other cores. Gneiss contains more mafic portions than other cores. These are typically hornblende chlorite magnetite rich. Carbonate veins and very minor disseminated sulfides in gneiss locally (preferentially associated with shears?):

Unique DDH#: 10171 DDH#: 1016 P295 File #: DH2951-267

Comments: Sericitic phyllite-argillite with minor goethite-red hematite and chert. Local red hematite replacing cubes (former pyrite?) in chert.

Unique DDH#: 10135 DDH#: 1018 P295 File #: DH2951-268

Comments: Rock is goethitic-graphitic phyllite. May contain minor disrupted chert beds. Minor limonite or quartz veins.

Unique DDH#: 10136 DDH#: 1019 P295 File #: DH2951-269

Comments: Locally brecciated chert goethite hematite magnetite iron formation over graphitic goethitic hematitic phyllite. Goethite-magnetite is locally vuggy and sinterly looking. The interval 238-243' contains pyrite (some arsenopyrite??) veins-laminae with minor quartz.

Unique DDH#: 10186 DDH#: 53 P295 File #: DH2951-270

Comments: Chert hematite goethite silicate iron formation, with minor quartz goethite veinlets. Upper part is hematitic (from surficial weathering??). Local vugs.

Unique DDH#: 10274 DDH#: S1 P295 File #: DH2951-271

Comments: Goethite hematite chert iron formation over silicate carbonate magnetite iron formation. Goethite hematite may be from surficial oxidation(?)

Unique DDH#: 12753 DDH#: MLCH-13 P295 File #: DH2951-272

Comments: Keweenawan rift fill sediments over chlorite quartz carbonate amphibole(?) talc plagioclase sericite mylonitic schist. Schist is sheared, with quartz carbonate k-feldspar veining. Not as much carbonate as other holes drilling the basal sediment contact. Protolith of schist is unknown, but is generally intermediate-mafic in nature. May contain minor disseminated pyrite(?).

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 12755 DDH#: KRCH-8 P295 File #: DH2951-273

Comments: Schistose quartz chlorite muscovite amphibole garnet metasediment-metavolcanic rock. Difficult to tell feldspar content. Interval 401-405' has 1-2 mm sulfide intraclasts. Rock appears to be bedded in general. Rock has local more mafic areas. Shearing has destroyed much of the original grain textures. Minor sulfide associated with quartz carbonate chlorite.

Unique DDH#: 10513 DDH#: 286-6/1 P295 File #: DH2951-274

Comments: Only samples are cuttings-fragments. Rock appears to have little feldspar (ultramafic?). Mica present appears to be a rock component and not contamination (rock is lamproitic?).

Unique DDH#: 12762 DDH#: ML-42C P295 File #: DH2951-275

Comments: Same lithologies as DRP drill cores. Sulfides in chert graphitic sulfide unit appear to have chalcopyrite. Brecciation in chert marble unit may be tectonic or may be related to hydrothermal deposition(?) on sea floor. Marble is locally tremolitic(?). Minor crosscutting veinlets-fractures have muscovite. Some may have minor amounts of grey sulfide (molybdenite?? galena??).

Unique DDH#: 10137 DDH#: 203 P295 File #: DH2951-276

Comments: Argillitic chert hematite goethite iron formation over graphitic sulfide phyllite schist. Core largely crushed, with identifiable fragments only below 195'. Colors of crushed core are 10R 2/4 (121-130', 140-145'), 10R 3/4 (130-140', 145-150', 230-235', 285-290'), 10R 4/4 (150-160', 185-190', 225-230', 265-270', 290-295'), 5YR 5/4 (160-165'), 10YR 4/2 (165-170'), 10YR 4/4 (170-175'), 5YR 5/2 (175-180'), 10YR 5/2 (180-185'), 5YR 4/4 (190-195', 200-205', 220-225', 235-255', 270-275', 295-305'), 5YR 3/4 (195-200', 205-210', 215-220', 275-280'), 10R 3/2 (210-215'), 10R 3/6 (255-265'), and 5R 2/4 (280-285').

Unique DDH#: 10142 DDH#: 208 P295 File #: DH2951-277

Comments: Only crushed core samples with local remaining fragments. Largely silicate goethite magnetite chert iron formation, with central portion of clayey limonite altered silicate iron formation(?). No core fragments below 235' although the lowermost recognized lithology appears to continue. Crushed core colors are 5YR 3/4 (110-115', 140-170', 210-220', 225-235', 240-245', 265-272'), 5YR 2/4 (115-120', 235-240'), 10YR 3/2 (120-135'), 5YR 3/2 (135-140'), 5YR 5/7 (170-175'), 5YR 4/4 (175-185', 200-210', 245-260'), 5YR 5/4 (185-190', 195-200'), 10YR 6/4 (190-195'), and 10R 3/4 (260-265', 220-225').

Unique DDH#: 12761 DDH#: ML-22 P295 File #: DH2951-278

Comments: Cuttings with recognizable rock fragments. No samples between 335-385'. Most of samples are overburden or dolomitic quartz marble with rare tremolite and epidote. Rock is somewhat schistose.

Unique DDH#: 12763 DDH#: ML-55CA P295 File #: DH2951-279

Comments: Keweenawan rift clastics over dolomitic quartz (recrystallized chert?) marble that is locally brecciated. Minor disseminated pyrite along some veinlets. Bottom sample taken has black chert clast. Some reduction spots in rift sediment have dark organic(??) matter as a nucleus (no noticeable odor).

Unique DDH#: 11445 DDH#: BM-3 P295 File #: DH2951-280

Comments: Phyllitic magnetite carbonate (dolomitic?) silicate(?) iron formation, and phyllitic laminae. Minor quartz veins, with minor sulfide veins and brecciation increasing with depth.

Unique DDH#: 12754 DDH#: KR-2 P295 File #: DH2951-281

Comments: Biotite quartz calcite muscovite schist (predominantly biotite?). Rock is generally crenulated. Minor quartz calcite veins with sulfide locally toward the base.

Unique DDH#: 10152 DDH#: 207 P295 File #: DH2951-282

Comments: Argillitic chert oxide silicate iron formation. Recognizable core fragments within 165-180' and below 265'. Rock is sheared deformed, including the chert and quartz veins(?). Oxides (originally magnetite?) are heavily altered to goethite and grey hematite with some limonite-red hematite in more siliceous-argillaceous portions. Core has pyrite locally below 305'. Amount of aluminosilicates may be from argillitic material or silicate chemical sediments. Crushed core colors are 5YR 4/4 (118-125, 140-150, 165-175, 220-225, 230-235, 240-255, 270-275, 290-295, 300-315'), 10YR 6/4 (125-130'), 10YR 5/4 (130-135'), 10R 5/6 (135-140'), 10R 4/6 (150-155'), 10R 3/6 (155-160, 260-265'), 10R 3/4 (160-165, 175-180'), 5YR 2/4 (180-190'), 5YR 3/2 (190-200'), 10R 2/4 (200-205'), 5YR 3/4 (205-220, 225-230, 235-240, 275-285'), 5YR 5/6 (255-260'), 10YR 4/4 (270-275, 285-290'), 5YR 5/4 (295-300').

Unique DDH#: 10154 DDH#: S1033 P295 File #: DH2951-283

Comments: Silicate (and carbonate?) magnetite iron formation that is oxidized at the top and bottom. Unit is locally folded and broken, with local quartz chlorite veins.

Unique DDH#: 10157 DDH#: S1034 P295 File #: DH2951-284

Comments: Oxide chert iron formation, with hematite and goethite replacing chert. Chert is locally bleached. Local brecciation, including quartz veins. Minor dolomite crystals in vugs.

Unique DDH#: 10159 DDH#: S15 P295 File #: DH2951-285

Comments: Chert goethite iron formation with minor red hematite and veinlets with a trace of pyrite.

Unique DDH#: 15509 DDH#: S20 P295 File #: DH2951-286

Comments: Sericitic phyllite with variable red hematite (alteration?). Minor late pyrite (or marcasite?) along some cleavage planes. Crushed core colors are 5R 5/2 (29-35'), 10R 6/4 (35-40') and 10R 5/6 (40-45').

Unique DDH#: 10337 DDH#: S21 P295 File #: DH2951-287

Comments: Brecciated chert goethite iron formation. Goethite appears to be locally replacing pyrite cubes. Quartz veins or recrystallized chert is fractured-brecciated with interstitial goethite. Crushed core sample colors are 5R 3/4 (28-30'), 10R 3/4 (30-45', 65-70', 80-82'), 10R 4/4 (45-55'), 5YR 4/4 (55-60', 75-80', 82-85'), 5YR 3/4 (60-65', 70-80') and 5R 4/4 (85-89').

Unique DDH#: 10130 DDH#: S1022 P295 File #: DH2951-288

Comments: Oxide chert iron formation. Appears to be fragmental (intraclastic?). Crushed core colors are 10R 3/6 (0-5, 25-30, 75-80, 95-100, 170-180'), 10R 3/4 (5-15, 20-25, 30-60, 65-75, 145-150, 180-190, 195-200), 5YR 3/4 (60-65, 150-155, 190-195'), 10R 2/4 (15-20), 5YR 4/4 (80-95, 100-145, 160-170'), and 5YR 4/4 (165-170').

Unique DDH#: 10212 DDH#: S1031 P295 File #: DH2951-289

Comments: Argillitic(?) slightly graphitic chert with minor sulfide. Could be silicified phyllite also. Crushed core colors are 10R 4/4 (75-80, 95-100, 110-115, 130-140'), 10R 3/6 (80-85, 90-95, 115-125'), 10R 4/6 (85-90, 100-105'), 10R 3/4 (105-110, 140-145'), 5R 3/4 (125-130'), 5YR 5/4 (145-150'), 5YR 3/4 (150-155'), 10YR 4/2 (155-160'), and 5YR 4/2 (160-162').

Unique DDH#: 10363 DDH#: S1029 P295 File #: DH2951-290

Comments: Laminated oxide chert iron formation. More hematitic magnetic toward top and goethitic toward base. Local quartz carbonate veinlets. Goethite hydrothermal?

Unique DDH#: 10357 DDH#: S1030 P295 File #: DH2951-291

Comments: Chert goethite hematite iron formation with goethite predominating. Goethite is locally brecciated with calcite cement.

Unique DDH#: 10214 DDH#: S222 P295 File #: DH2951-292

Comments: Oxide chert iron formation. More goethitic and quartz veins toward the base.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10215 DDH#: S223 P295 File #: DH2951-293

Comments: Generally goethite chert iron formation, with limonite alteration and minor disseminated pyrite and quartz veins.

Unique DDH#: 10368 DDH#: S224 P295 File #: DH2951-294

Comments: Goethite predominating oxide chert iron formation. Locally brecciated and vuggy, possibly from hydrothermal brecciation.

Unique DDH#: 10370 DDH#: S1036 P295 File #: DH2951-295

Comments: Locally argillaceous goethite hematite chert iron formation, with minor goethite quartz veinlets.

Unique DDH#: 10034 DDH#: S1040 P295 File #: DH2951-296

Comments: Silicate magnetite chert iron formation, with quartz carbonate biotite (minor muscovite and/or chlorite??) veins. May contain minor disseminated sulfide near 31'(?).

Unique DDH#: 10198 DDH#: S1046 P295 File #: DH2951-297

Comments: Silicified chert silicate oxide(?) iron formation with minor goethite quartz veinlets. Rock contains little iron oxides.

Unique DDH#: 10199 DDH#: S1033 P295 File #: DH2951-298

Comments: Brecciated(?) chert limonite goethite iron formation with minor magnetite. Chert heavily recrystallized, although some could be vein quartz.

Unique DDH#: 10285 DDH#: 276 P295 File #: DH2951-299

Comments: Silicate magnetite carbonate iron formation cut by goethite quartz pyrite alteration and veining. Top of silicate magnetite carbonate iron formation has chlorite, biotite tourmaline, quartz vein. Tourmaline may be remobilization of tourmalinite laminae(?) in that same portion. Thin 1.5 cm, weird breccia at about 139'. Lower goethitic portion is somewhat calcareous.

Unique DDH#: 10203 DDH#: S720 P295 File #: DH2951-300

Comments: Chert and graphitic(?) Mn oxide(?) goethite magnetite grey hematite iron formation. Magnetite amount is small. Black coloration identity in iron formation is uncertain. Chert appears tuffaceous-fragmental locally (silicified tuff?). Small amount of pyrite locally.

Unique DDH#: 10317 DDH#: S-2-55 P295 File #: DH2951-301

Comments: Red hematite chert goethite iron formation. Rock is locally fragmental-tuffaceous(?). Dark hematite-Mn oxides(?) along some veins.

Unique DDH#: 11065 DDH#: 10 P295 File #: DH2951-302

Comments: Weathered, clayey goethitic silicate magnetite carbonate(?) sulfide iron formation; getting less weathered and containing minor chert with depth. No recognizable core fragments above 150'. Sulfate (oxidation of sulfides?) occurs below 135'. Veinlets with dark chlorite below 200'. Vein with quartz(?), grey hematite(?) and tourmaline within 205-210'. Crushed core colors are 5YR 3/4 (75-80, 85-95, 150-160, 175-180, 210-270'), 5YR 4/4 (80-85, 100-105, 130-135'), 10YR 4/4 (95-100'), 5YR 4/6 (105-110, 123-130, 135-145'), 10R 4/6 (110-120'), 5YR 5/6 (120-123'), 5YR 3/2 (145-150'), 10YR 4/2 (160-165, 180-210'), and 10YR 3/2 (165-175').

Unique DDH#: 10205 DDH#: 204 P295 File #: DH2951-303

Comments: Predominantly chert goethite over predominantly silicate carbonate iron formation. No core above 235'. Cuttings colors are 10YR 6/2 (150-155'), 10R 5/2 (155-160'), 5YR 3/1 (160-165'), 10R 4/6 (165-170'), 5YR 4/4 (170-175, 250-255'), 5YR 3/4 (175-200, 235-250, 255-265, 275-295'), 10YR 4/4 (200-225'), 10YR 3/2 (225-230'), 10YR 4/2 (230-235') and 10YR 4/6 (265-275').

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10143 DDH#: 206 P295 File #: DH2951-304

Comments: No core above 230' (regolith??). The interval 230-240' is vuggy-weathered. Rock is rather calcareous, with original textures obscured. Original rock was finer gabbro or coarser basalt (porphyritic?). Calcite veins have quartz and pyrite with depth. Cuttings colors are 10YR 6/4 (116-125'), 10YR 5/2 (125-130, 135-140'), 5YR 5/1 (130-135'), 10YR 4/2 (140-145, 200-205'), 5YR 6/4 (145-150, 155-160'), 5YR 7/4 (150-155'), 5YR 5/6 (160-165'), 10YR 4/4 (165-175, 225-230'), 5YR 4/4 (175-180, 185-190'), 5YR 4/6 (180-185'), 5YR 3/4 (190-200, 205-210'), 10YR 5/6 (210-215'), 5YR 6/6 (215-225'), and 10YR 7/2 (230-235').

Unique DDH#: 10144 DDH#: 205 P295 File #: DH2951-305

Comments: Only recognizable rock fragments within 205-215'. This is goethitic limonitic iron formation, probably resulting from surficial oxidation(?). Contains minor carbonate and white kaolin(?). Cuttings colors are 10YR 5/2 (137-140'), 10YR 6/4 (140-145'), 10YR 4/4 (145-150, 215-220'), 5YR 4/4 (150-155'), 10YR 5/6 (155-160'), 5YR 4/6 (160-170, 175-185, 195-200, 205-210'), 5YR 3/6 (170-175, 200-205'), 10R 3/6 (185-195'), and 5YR 5/6 (210-215, 220-227').

Unique DDH#: 10146 DDH#: 202 P295 File #: DH2951-306

Comments: Only scattered recognizable rock fragments within 170-195'. These are limonitic phyllite and goethite magnetite iron formation. Phyllite is yellow tan limonitic and is fragmental(?) tuffaceous(?). Minor sulfide veining in the lowermost phyllite. Cuttings colors are 10YR 7/2 (55', 150-155'), 5Y 6/1 (55-72'), 10 YR 6/2 (72-105'), 5YR 4/6 (105-110'), 5YR 4/4 (110-125, 160-180'), 5YR 6/4 (125-130'), 10YR 5/4 (130-150'), 10YR 5/2 (155-160'), 5YR 3/4 (180-190'), 5YR 5/6 (190-195'), and 10YR 4/2 (195-200').

Unique DDH#: 10015 DDH#: BM-5 P295 File #: DH2951-307

Comments: Graphite pyrrhotite chert iron formation with minor cherty tuff downhole. Pyrite locally replaces pyrrhotite. Local folding, brecciation, and quartz carbonate veins (latter especially downhole).

Unique DDH#: 10004 DDH#: G-6 P295 File #: DH2951-308

Comments: Graphite pyrite chert phyllite with minor cherty tuff and tourmalinite layers. Local coarser more schistose amphibolitic (with tourmaline?) portion within 95-100'. Commonly finely laminated.

Unique DDH#: 10003 DDH#: G-5 P295 File #: DH2951-309

Comments: Graphite pyrite chert phyllite with minor cherty tuff(?) and magnetite portions. Commonly finely laminated. Local quartz pyrite veins. Pleochroic tourmaline in darker laminae.

Unique DDH#: 10005 DDH#: G-8 P295 File #: DH2951-310

Comments: Graphite pyrite chert phyllite with minor cherty and calcareous tuff and amphibolitic (with tourmaline?) portions. Commonly finely laminated. Local quartz pyrite carbonate veins.

Unique DDH#: 10009 DDH#: BM-12F P295 File #: DH2951-311

Comments: Altered intermediate (perhaps felsic?) volcanics. Rock was probably tuffaceous originally. Rock is calcareous-micaceous, with sulfide also resulting from alteration (or chemical sedimentation?). Shears-veins with pale muscovite, sulfide, quartz, goethite and calcite. Rock has altered phenocrysts, amygdalites and/or volcaniclasts.

Unique DDH#: 10014 DDH#: BM-4 P295 File #: DH2951-312

Comments: Sulfide graphite chert silicate iron formation with felsic tuff (siliceous) below intermediate(?) volcanics (chloritic micaceous schist). Graphite sulfide chert iron formation is phyllitic, brecciated to folded, with local siliceous (felsic?) tuff layers. Sulfide predominantly pyrrhotite with secondary pyrite. Possibly some black schist chloritic alteration in the upper portion of the sulfide iron formation unit.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10012 DDH#: BM-2 P295 File #: DH2951-313

Comments: Sulfide graphite chert silicate iron formation with felsic tuff (siliceous, with iron carbonate). Graphite sulfide chert iron formation is phyllitic, brecciated to folded, with local siliceous (felsic?) tuff layers. Sulfide predominantly pyrrhotite with secondary pyrite. Sulfide and graphite decrease in general with depth, with silicate iron formation increasing.

Unique DDH#: 10097 DDH#: 87 P295 File #: DH2951-314

Comments: Chlorite sulfide graphite carbonate iron formation over siliceous tuff, chert and chert conglomerate. Chemical sediment is more coarsely recrystallized, and may be a product of hydrothermal alteration. Tuff is fragmental, siliceous and slightly graphitic. Chert clasts are elongate and generally rounded. They may be intraclastic, or tectonically produced. They are typically in distinct beds/layers.

Unique DDH#: 10031 DDH#: 79 P295 File #: DH2951-315

Comments: Sulfide graphite chert silicate carbonate iron formation over a chloritic biotitic siliceous semischist (recrystallized?). Basal material may be a hydrothermal alteration product (dark, fine-grained) of a tuffaceous unit(?). Contains local veins/segregations with quartz chlorite pyrite and minor dolomite, and brecciated or conglomeratic chert (or quartz veins??). Flattened clasts (tuff?) are recognizable in the vicinity of the contact between the units.

Unique DDH#: 10030 DDH#: 78 P295 File #: DH2951-316

Comments: Graphite sulfide chert iron formation over dark siliceous (and carbonate) tuffaceous semischist. Some chert conglomeratic layers near contact. Tuff may be somewhat chloritic/biotitic. Tuff is altered(?), and/or contains silicate carbonate iron formation layers with porphyroblastic needles of amphibole(?) pyroxene(?) or tourmaline(?) (probably amphibole). Chert conglomerate could be tectonic.

Unique DDH#: 10029 DDH#: 73 P295 File #: DH2951-317

Comments: Sulfide chert graphite iron formation over dark, siliceous tuff, with local chert conglomerate near contact. Tuff is chloritic-biotitic(?). Chert is locally brecciated, and "conglomeratic" chert may also have this origin.

Unique DDH#: 10033 DDH#: 82 P295 File #: DH2951-318

Comments: Graphite chert sulfide iron formation (locally tuffaceous) over carbonate silicate iron formation with local amphibole needles similar to DDH 78 (10030). Iron formation also has minor chert and stratiform pyrrhotite. As in other sulfide iron formation, pyrite is later than pyrrhotite. Trace chalcopyrite(?) in some veins.

Unique DDH#: 10017 DDH#: BM-7 P295 File #: DH2951-319

Comments: Kaolinitic regolith developed on graphite sulfide chert iron formation with tuff. Becomes less deformed, more cherty and tuffaceous with depth.

Unique DDH#: 15510 DDH#: SR-1 P295 File #: DH2951-320

Comments: Very calcareous chlorite biotite quartz schist, with carbonate pyrite veins with quartz and possibly K-feldspar. Protolith was probably intermediate-mafic volcanics (flows and tuffs or sheared flows). Probably basaltic; more biotitic schistose portions may just result from shearing and alteration.

Unique DDH#: 15511 DDH#: SR-3 P295 File #: DH2951-321

Comments: Locally pillowd(?) metabasalt over more schistose sericite chlorite quartz carbonate metatuff(?). Mafic dyke with chilled margins essentially in between other rock types. Dyke magnetic and relatively fresh except for late calcite veins (Keweenawan?). Several feet of metabasalt occur in center of dyke. Sulfides predominantly in metabasalt. Not as calcareous as other SR cores, but still altered.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 15512 DDH#: SR-2 P295 File #: DH2951-322

Comments: Graphite sulfide phyllite over very calcareous chlorite biotite quartz schist, with carbonate pyrite veins with quartz and possibly K-feldspar. Protolith was probably intermediate-mafic volcanics (flows and tuffs or sheared flows). Probably basaltic(?); more biotitic schistose portions may just result from shearing and alteration.

Unique DDH#: 10556 DDH#: SL-1 P295 File #: DH2951-323

Comments: Tuffaceous chlorite sericite actinolite(?) schist over sulfide graphite iron formation over tuffaceous graphitic pyritic chert with magnetite garnet sillimanite(?) or tremolite(?) or wollastonite(?) schist and garnet chlorite schist. Acicular radiating masses of silicates (associated with garnet and magnetite) is probably amphibole or sillimanite. Metamorphic mineralogy is probably preferentially superimposed on some kind of hydrothermal alteration chemistry. May or may not be hydrothermal system related metamorphism. Footwall-hanging wall relations are uncertain. Neat rock. Base of the upper tuffaceous schist has alteration to kaolin, sulfates, or clays (no discernible taste). Sulfides occur throughout in variable amounts.

Unique DDH#: 10560 DDH#: CK-1 P295 File #: DH2951-324

Comments: Only cuttings rock fragments. Predominantly sericitic phyllite-phyllitic schist. The interval 475-485' contains quartz K-feldspar veins with associated(?) pyrite. Granite veins?? Sulfide may also be remobilized.

Unique DDH#: 10561 DDH#: CK-2 P295 File #: DH2951-325

Comments: Only cuttings rock fragments. Predominantly sericitic phyllite-phyllitic schist. Lower portion contains quartz K-feldspar veins, with(?) sulfides. Could be remobilized sulfides. Granite veins??

Unique DDH#: 10562 DDH#: CK-3 P295 File #: DH2951-326

Comments: Only cuttings rock fragments. Predominantly sericitic phyllite-phyllitic schist. Upper portion contains quartz K-feldspar veins, but no pyrite. Granite veins?? Central portion has dolomitic marble (could be chemical sediments or veins).

Unique DDH#: 10563 DDH#: CK-4 P295 File #: DH2951-327

Comments: Only cuttings rock fragments. Predominantly sericitic phyllite-phyllitic schist. Lower portion contains quartz K-feldspar veins, but with no pyrite. Granite veins??

Unique DDH#: 10564 DDH#: CK-5 P295 File #: DH2951-328

Comments: Only cuttings rock fragments. Predominantly sericitic phyllite-phyllitic schist. Upper portion contains quartz K-feldspar veins, but without pyrite. Granite veins?? Lower sericitic phyllite contains sulfide chemical sediments (and veins?-may be remobilized).

Unique DDH#: 10565 DDH#: HM-1 P295 File #: DH2951-329

Comments: Sericitic phyllitic schist and phyllitic marble. Local pyrite chemical sediment and K-feldspar.

Unique DDH#: 10544 DDH#: MM-1 P295 File #: DH2951-330

Comments: Few fragments of parent rock appear to be amphibolitic granite, amphibolite and chlorite schist-phyllite. Rock is clayey and altered down to bottom.

Unique DDH#: 10545 DDH#: MM-2 P295 File #: DH2951-331

Comments: Only cuttings with small rock fragments making identification difficult. Rock appears to be altered(?) mafic igneous, with local coarse hornblende(?).

Unique DDH#: 10553 DDH#: EF-1 P295 File #: DH2951-332

Comments: Variably siliceous sericitic phyllitic schist with granitic-quartz veins. Locally somewhat calcareous. Basal sample has minor sulfide (chemical sediments??).

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10558 DDH#: MG-2 P295 File #: DH2951-333

Comments: Variably graphitic sericitic phyllitic schist with minor argillitic marble over the same with minor pyritic chemical sediment. Bottom unit is locally chloritic or tuffaceous with local feldspar phenocrysts and quartz eyes. Quartz and dolomite predominating veins in the upper portion become more quartz and pyrite predominating with depth (remobilization of country rock?). More chloritic with depth(?). Rock mylonitic to locally brecciated with local folds/kinks. K-feldspar also developed in some veins (heat provided by mylonitization??).

Unique DDH#: 10557 DDH#: MG-1 P295 File #: DH2951-334

Comments: Rock fabric strongly developed as in MG-2, with folding and multiple slip surfaces. Coarser (fine-to medium-grained) tuffaceous slices have by contrast little internal fabric development. Volcanic contribution problematic. "Tuffaceous slices" such as within 348-390' locally have quartz eyes, feldspar phenocrysts, and tend to be carbonate bearing. The interval 324-344' appears to be coarser (cm's??) fragmental (where deformation hasn't quite smeared out the textures?). Such fragments could be primary or they could result from deformation. The unit at 210-220' could be recrystallized silicified tuff, siliceous clastic, or even in part quartz vein. Henk says to note good sedimentary features (foreset cross-beds) near 186'.

Unique DDH#: 10559 DDH#: MG-4 P295 File #: DH2951-335

Comments: More sericitic phyllite and phyllitic schist, with more tuffaceous (at least coarser, recognizable compared to the phyllite, should that have a tuffaceous component) and chloritic material with depth. Minor granitization occurs in the more sericitic stuff (probably more of a solid state recrystallization?). A lot of dolomite and lesser calcite around. Minor epidote associated with some of the more igneous looking granite (not noted in log). All vein materials may be locally derived-sweated out.

Unique DDH#: 10566 DDH#: MG-3 P295 File #: DH2951-336

Comments: More sericitic phyllite and phyllitic schist, with more tuffaceous (at least coarser, recognizable compared to the phyllite, should that have a tuffaceous component) and perhaps chloritic material with depth. Minor vein granite (with some epidote and pyrite) occurs in the lowermost unit. Not as much carbonate as some of the previous holes of this series. Local porphyroblastic dolomite occurs locally. All vein materials may be locally derived-sweated out. Recrystallization of quartz makes the separation of disrupted chert beds and stratiform quartz veins not possible.

Unique DDH#: 12757 DDH#: ML-27 P295 File #: DH2951-337

Comments: Only cuttings. Largely sericitic phyllitic schist, muscovite quartz schist, and minor carbonate (latter decreases downward?). Local quartz hornblende amphibolite (usually with carbonate), although this has enough plagioclase and "igneous texture" to look intrusive. Minor "granitization", especially in upper part of basal unit. Minor disseminated pyrite within 215-220' (associated with porphyroblastic carbonate?).

Unique DDH#: 10554 DDH#: KRCH-6 P295 File #: DH2951-338

Comments: "Greenstone" looking mafic to intermediate metavolcanics (chlorite, actinolite, biotite, quartz, carbonate, feldspar? schist). Locally pillowed and coarsely fragmental. Much carbonate alteration and veins. Quartz or minor sulfides (including chalcopyrite or bornite) associated with some veins. Rock has local dikes-veins of fine- to medium-grained dacite(?). Some "brecciation" could be tectonic, but is probably more primary. Percent of mafics increase(?) downhole. Some quartz veins may have minor feldspar associated with them. Carbonate is predominating material between pillows and fragments. Boxes of core missing at 276-286' and 488-498'.

Unique DDH#: 10555 DDH#: KRCH-7 P295 File #: DH2951-339

Comments: Predominantly mafic metavolcanics and sills (porphyritic), with minor pillows and more felsic (thin) volcanics. Most of rock is schistose chlorite and actinolite, with other materials more siliceous and/or biotitic. Disseminated sulfide (pyrite, pyrrhotite, and lesser chalcopyrite, and bornite) and carbonate alteration amounts occur predominantly in material between the mafic volcanics or intrusives. Carbonate veins fairly common with lesser quartz. More calcite than dolomite compared with KRCH-6. Local boxes of core missing (187-197', 254-263', 407-416', 484-494', 577-587', 619-629', and 726-735')

Unique DDH#: 14524 DDH#: P-11 P295 File #: DH2951-340

Comments: Amphibolitic schist and amphibole, biotite, quartz, plagioclase, K-feldspar gneiss with local igneous textures (neosome??). Much feldspar appears perthitic. Minor disseminated pyrite, especially in amphibolitic schist portions.

Unique DDH#: 14523 DDH#: P-12 P295 File #: DH2951-341

Comments: Biotite, quartz, K-feldspar, plagioclase schist and gneiss. Local porphyroblastic K-feldspar. Kaolinitic-clay weathering at top and along fractures.

Unique DDH#: 14734 DDH#: PX-1 P295 File #: DH2951-342

Comments: Rift clastics over mixed gneisses and schists. Rift clastics are variably hematitic, but are locally reduced. Sediments vary from mudstone to very coarse angular grains. Gneisses and schists are intermixed, with local igneous textures. They vary from being mafic rich to quartzofeldspathic. The older rocks appear to be altered near the unconformity (clays, chlorite?, kaolin?). The older rocks contain dolomite veins. More mafic portions (only?) have minor disseminated pyrite. Rock locally pegmatoidal.

Unique DDH#: 14525 DDH#: P-9 P295 File #: DH2951-343

Comments: Mica feldspar quartz (garnet?) schist with shears, quartz K-feldspar veins with local chlorite and sericite (muscovite). Minor carbonate and disseminated pyrite. Porphyroblastic garnet (soft) or carbonate (less likely?). Protolith greywacke??. Believed to be Penokean deformed Proterozoic sediment not Archean.

Unique DDH#: 14492 DDH#: 264-7/2 R1 P295 File #: DH2951-344

Comments: Mylonitic granite schist-gneiss with abundant biotite and lesser muscovite. Core is somewhat magnetic from magnetite. Muscovite alteration product along with carbonate and epidote. Some pinitive looking muscovite along slip surfaces (from altering cordierite??).

Unique DDH#: 15049 DDH#: 285-25/2 R1 P295 File #: DH2951-345

Comments: Biotite hornblende pyroxene(?) magnetite granite. Occurs as fine- to medium-grained phase and a coarser intrusive phase (remelting of former?). Rocks have a variety of textures, and several phases may be represented. May get more plagioclase rich (albitization???) with depth. Rock is moderately magnetic (disseminated magnetite). Pyrite occurs as disseminated grains, and locally along fractures in coarser portions.

Unique DDH#: 10636 DDH#: 18974 P295 File #: DH2951-346

Comments: Greenish argillite (Virginia Formation presumably) over variably graphitic argillite (with variable carbonate also). Minor calcite veins. Minor pyrite disseminations. Fissility or other fabric weakly developed if at all. Coarser arenitic laminae with rare(?) slump(?) folds. More graphitic downwards(?). More carbonate toward top(?).

Unique DDH#: 10638 DDH#: 3796 P295 File #: DH2951-347

Comments: Generally argillitic and sideritic rock with minor chert and variable graphite. May contain dark iron (or Mn?) oxides. Chert is recrystallized and appears to contain crystal casts (from pyrite?? or evaporites????). Minor calcite and quartz(?) veinlets.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10640 DDH#: 4072 P295 File #: DH2951-348

Comments: Largely variably graphitic argillite with carbonate and sulfide chemical sediment and minor chert. Local melanterite surface oxidation locally. Minor goethitic (and magnetite?) iron formation at the very top of the core.

Unique DDH#: 10637 DDH#: 3795 P295 File #: DH2951-349

Comments: Variably graphitic argillite with chert, carbonate and sulfide chemical sediment over orthoquartzite with local pyrite. Local melanterite surface oxidation locally. Most graphitic and argillitic stuff is within 360-522'. Cherty and quartzite (and carbonate?) rock is locally fragmental and/or pelletoidal(?) with quartz cement. Stylolites often have associated pyrite. Dark laminae within carbonate and chert (within 462-472') may contain pleochroic tourmaline(???????) or hornblende(????????). Very fine-grained. Interesting textures.

Unique DDH#: 10639 DDH#: 3987 P295 File #: DH2951-350

Comments: Orthoquartzite with minor red hematite and limonite staining.

Unique DDH#: 10635 DDH#: 18972 P295 File #: DH2951-351

Comments: Ninety plus feet of good overburden core over kaolinitic regolith developed from variably graphitic fissile argillite-shale. At base of overburden above the kaolin is a fragment of argillite which may be some glacially overthrust material. Some of this sediment above the kaolin could be Cretaceous, but the fissile graphitic argillite is Virginia Formation. Fissility is relatively prominent, but is still less than a typical slate or phyllite.

Unique DDH#: 14563 DDH#: LV-2A P295 File #: DH2951-352

Comments: Dark green, very fine-grained silicate with lesser oxide and carbonate iron formation. Contains chert or quartz arenite with silica cement. Chalcedony also replacing iron formation, perhaps associated with fragmental (pelletoidal?) iron formation. Fragments may be intraclasts or remnants from silicification(?).

Unique DDH#: 14562 DDH#: LV-1 P295 File #: DH2951-353

Comments: Quartz feldspar gneiss with hornblende, epidote and chlorite. Local neosome or local remelting. Minor veinlets with red hematite, quartz, or epidote.

Unique DDH#: 11909 DDH#: 18695 P295 File #: DH2951-354

Comments: Argillite with variable graphite (generally minor), and minor carbonate laminae. Rock contains soft(?) sediment slumps, with variable bedding angles. Minor disseminated pyrite and carbonate veinlets.

Unique DDH#: 10631 DDH#: TL-5 P295 File #: DH2951-355

Comments: Argillite with variable graphite (generally minor). Rock contains soft(?) sediment slumps, small folds, bedding angles at about 45 degrees to core axis..

Unique DDH#: 10628 DDH#: TL-1 P295 File #: DH2951-356

Comments: Variable graphitic argillite (generally little graphite). Upper portion of samples are kaolinitic (regolith), with the upper 10' being graphitic (Cretaceous lignite??). Minor soft sediment slumping in argillite, which is probably Virginia Formation. Minor limonite and bluish staining within 320-325'.

Unique DDH#: 10629 DDH#: TL-2 P295 File #: DH2951-357

Comments: Variable graphitic argillite (generally little graphite). Upper portion of samples are Cretaceous (some lignite??), below which is kaolinitic material. Minor soft sediment slumping in argillite, which is probably Virginia Formation. Kaolinitic weathering of Virginia Formation decreases with depth.

Unique DDH#: 10630 DDH#: TL-3 P295 File #: DH2951-358

Comments: Variable graphitic argillite (generally little graphite). Upper portion of samples are Cretaceous (some lignite??), below which is kaolinitic material. Minor soft sediment slumping in argillite, which is probably Virginia Formation. Kaolinitic weathering of Virginia Formation decreases with depth.

Unique DDH#: 10632 DDH#: TL-4 P295 File #: DH2951-359

Comments: Other TL holes are borderline phyllitic, with variable bedding angles and soft sediment deformation. This is the only one of the series with minor chert and slightly magnetic iron silicate oxide chemical sediments (relatively minor, and predominantly toward the top). Toward base is quartz K-feldspar carbonate pyrite chlorite vein which may contain sphalerite, iron carbonate or barite. Interesting - this is stuck out in the middle of the Virginia Formation. Unit is very carbonaceous locally.

Unique DDH#: 10633 DDH#: 18971 P295 File #: DH2951-360

Comments: Laminated Virginia Formation. Minor soft sediment deformation. Gentle dips. Minor carbonate and disseminated pyrite. Kaolinitic at the top with local graphitic-lignite(?) fragments (glacial sediment?).

Unique DDH#: 10634 DDH#: 18973 P295 File #: DH2951-361

Comments: Greenish-reddish (more purple) argillite over variably graphitic argillite with minor sulfides. Upper part may be oxidized equivalent of the other. Upper part contains several brecciated portions. Very graphitic locally. Virginia Formation.

Unique DDH#: 12756 DDH#: MLCH-8 P295 File #: DH2951-362

Comments: Generally quartz biotite chlorite muscovite garnet schist, lesser coarser-grained quartz hornblende (and plagioclase) diorite or gneiss, and minor marble. Probably metasediment or metavolcanics (generally intermediate to felsic?). Occasional minor folds. Minor sulfide associated with veins or segregations. Quartz veins locally have plagioclase, mica or hornblende. Rock may be more siliceous-felsic with depth.

Unique DDH#: 12771 DDH#: ML-49C P295 File #: DH2951-363

Comments: Keweenawan Rift sediment over mica quartz schist over recrystallized siliceous marble (same as in DRP-1 etc.). Mica schist is altered-weathered (clayey, kaolinitic?). Schist becomes graphitic toward the contact with the marble (some sulfides). Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Marble is more(?) calcareous upward, with local stylolites. Schist locally brecciated(?). Rift sediment unconformity not as calcareous-dolomitic as some other cores.

Unique DDH#: 12768 DDH#: ML-43C P295 File #: DH2951-364

Comments: Keweenawan Rift sediment over mica quartz schist over recrystallized siliceous marble (same as in DRP-1 etc.). Mica schist is altered-weathered (clayey, kaolinitic?). Schist doesn't become as graphitic toward the contact with the marble (some sulfides) as ML-49c, but otherwise pretty similar. Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Rift sediment unconformity not as calcareous-dolomitic as some other cores.

Unique DDH#: 12772 DDH#: ML-50C P295 File #: DH2951-365

Comments: Keweenawan Rift sediment over mica quartz schist over recrystallized siliceous marble (same as in DRP-1 etc.). Mica schist is altered-weathered (clayey, kaolinitic?). Pretty similar to previous cores. Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Rift sediment unconformity not as calcareous-dolomitic as some other cores. Schist with chlorite (more than other cores?, some dark greyish?) may contain cordierite(?). Minor veinlets in marble with vugs and disseminated sulfides.

Unique DDH#: 12773 DDH#: ML-51C P295 File #: DH2951-366

Comments: Keweenawan Rift sediment over recrystallized siliceous marble (same as in DRP-1 etc.). Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Much of this appears brecciated and recrystallized. Rift sediment unconformity not as calcareous-dolomitic as some other cores. Minor veinlets in marble with vugs and disseminated sulfides.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 12749 DDH#: T-4 P295 File #: DH2951-367

Comments: Cross laminated, poorly cemented quartz arenite with limonite (and minor red hematitic) staining. Looks like Cambrian.

Unique DDH#: 10517 DDH#: T-5 P295 File #: DH2951-368

Comments: Fine-grained tuffaceous chloritic carbonate schist with graphitic clasts and minor pyrite

Unique DDH#: 10518 DDH#: T-6 P295 File #: DH2951-369

Comments: Fine-grained tuffaceous graphitic chloritic carbonate(?) phyllite-schist with minor pyrite. Local folds and quartz pyrite veins.

Unique DDH#: 10614 DDH#: T-3 P295 File #: DH2951-370

Comments: Laminated to finely bedded (graded) tuffaceous phyllite with chlorite, sericite and graphite. May contain minor sulfide chemical sediment (now porphyroblastic that is oxidizing to limonite).

Unique DDH#: 14495 DDH#: AB-10 P295 File #: DH2951-371

Comments: Mylonitic plagioclase, K-feldspar, quartz, biotite, muscovite, chlorite schist and gneiss. Chlorite, muscovite and red hematite are strictly alteration products. Disseminated pyrite occurs throughout.

Unique DDH#: 14597 DDH#: AB-24A P295 File #: DH2951-372

Comments: Graphite sulfide phyllite, with minor siderite, and quartz pyrite veins. Local fold closures and strain slip cleavage. Some pyrite porphyroblastic.

Unique DDH#: 12776 DDH#: ML-54C P295 File #: DH2951-373

Comments: Keweenawan Rift sediment over mica quartz schist with brecciated pillow basalt over recrystallized siliceous marble (similar to in DRP-1 etc.). Mica schist is altered-weathered (clayey, kaolinitic?, hematitic). Lower part of unit with schist is brecciated basalt (pillowed) which may be the protolith of the schist. Schist and marble contact is laminated (from shearing?). Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Rift sediment unconformity not as calcareous-dolomitic as some other cores.

Unique DDH#: 12270 DDH#: ML-45C P295 File #: DH2951-374

Comments: Keweenawan Rift sediment over mica quartz schist over recrystallized siliceous marble (same as in DRP-1 etc.). Mica schist is somewhat altered-weathered (clayey, kaolinitic?, hematitic?). Schist becomes graphitic and sulfide bearing toward the contact with the marble. This includes minor covellite and chalcopyrite. This is the "most" copper bearing of any holes in this sequence so far. Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Schist locally brecciated(?). Rift sediment unconformity not as calcareous-dolomitic as some other cores. Phyllite (tectonic sliver?) in marble not as deformed schistose as the schist. Hairline veins with pyrite crystals more common than normal in the marble.

Unique DDH#: 12775 DDH#: ML-53C P295 File #: DH2951-375

Comments: Keweenawan Rift sediment over mica quartz schist over recrystallized siliceous marble (same as in DRP-1 etc.). Mica schist is altered-weathered (clayey, kaolinitic?, hematitic?). Schist becomes graphitic toward the contact with the marble (some sulfides, including bornite). Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Schist locally appears fragmental (brecciated?). Local quartz K-feldspar may be recrystallized felsic tuff(?). Schist marble contact area has some skarn-like veining-alteration. Rift sediment unconformity not as calcareous-dolomitic as some other cores. Minor disseminated sulfides along fractures in marble.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 12769 DDH#: ML-44C P295 File #: DH2951-376

Comments: Keweenawan Rift sediment over mica quartz schist over recrystallized siliceous marble (same as in DRP-1 etc.). Mica schist is somewhat altered-weathered (clayey, kaolinitic?, hematitic?). Schist becomes graphitic toward the contact with the marble (some sulfides). Marble layers and skarn calc silicates near schist marble contact also. Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Schist locally appears fragmental (brecciated?). Local quartz K-feldspar may be recrystallized felsic tuff(?). Marble has disseminated sulfides along veinlets. Rift sediment unconformity not as calcareous-dolomitic as some other cores.

Unique DDH#: 12777 DDH#: ML-56C P295 File #: DH2951-377

Comments: Keweenawan Rift sediment over mica quartz schist over recrystallized siliceous marble (same as in DRP-1 etc.). Mica schist is somewhat altered-weathered (clayey, kaolinitic?, hematitic?). Schist becomes graphitic toward the contact with the marble (some sulfides). Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Schist locally appears fragmental (brecciated?). Schist marble contact is sheared and brecciated, with numerous stylolites nearby. Marble has disseminated sulfides along veinlets, including minor bornite. Rift sediment unconformity not as calcareous-dolomitic as some other cores.

Unique DDH#: 12778 DDH#: MLCH-10 P295 File #: DH2951-378

Comments: Keweenawan Rift sediment over recrystallized siliceous marble (same as in DRP-1 etc.). Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Rift sediment unconformity not as calcareous-dolomitic as some other cores. Insoluble accumulations or sediment fills in fractures in siliceous marble down to 303'. Some stylolites.

Unique DDH#: 12774 DDH#: ML-52C P295 File #: DH2951-379

Comments: Probably glacially reworked Keweenawan Rift fill and perhaps Cambrian sandstone over weathered schist(?) or schist cobble(?) at base. Strange.

Unique DDH#: 12780 DDH#: KRCH-1 P295 File #: DH2951-380

Comments: Chlorite garnet quartz carbonate amphibole biotite muscovite schist. This contains quartz rich layers-patches with coarse hornblende, minor carbonate and local plagioclase. These could be from variations in the protolithology such as carbonate content (iron carbonate concretions??), or perhaps veins or intrusives although these are very irregular. Other later (cross cutting) veins or segregations of quartz, chlorite, carbonate (and plagioclase?) also occur. Minor disseminated and vein associated pyrite-chalcopyrite occurs locally. Laminated nature of materials probably indicates a tuff or sediment protolith.

Unique DDH#: 12779 DDH#: MLCH-6 P295 File #: DH2951-381

Comments: Mica quartz schist (possibly? with brecciated pillow basalt) over recrystallized siliceous marble (similar to in DRP-1 etc.). Mica schist is variably hematitic. "Brecciated basalt (pillowed)" is well deformed so interpretation is problematical. Schist and marble contact is less gradational than usual (sheared?). Quartz "clasts" vary from pebble like to irregular (void filling? or breccia fragments). Probably tectonic. Unit locally very siliceous.

Unique DDH#: 12781 DDH#: D-1 P295 File #: DH2951-382

Comments: Chlorite garnet quartz carbonate amphibole biotite muscovite schist. This contains quartz rich layers-patches with coarse hornblende, minor carbonate and local plagioclase(?). These could be from variations in the protolithology such as carbonate content (iron carbonate concretions??), or perhaps veins or intrusives although these are very irregular. Other later (cross cutting) veins or segregations of quartz, biotite, chlorite, carbonate (and plagioclase?) also occur. Minor disseminated and vein associated pyrite occurs locally. Laminated nature of materials probably indicates a tuff or sediment protolith. Vague textural remnants of coarser clasts-fragmentals are locally preserved (260-270'?).

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 12782 DDH#: D-2 P295 File #: DH2951-383

Comments: Chlorite garnet quartz carbonate amphibole biotite muscovite schist cut by a magnetic basalt dike (Keweenawan?). Schist contains quartz rich layers-patches with coarse hornblende, minor carbonate and local plagioclase(?). These could be from variations in the protolithology such as carbonate content (iron carbonate concretions??), or perhaps veins or intrusives although these are very irregular. Other later (cross cutting) veins or segregations of quartz, biotite, chlorite, carbonate (and plagioclase?). also occur. Minor shears-veins in basalt contain calcite and chlorite. Minor disseminated and vein associated pyrite occurs locally. Laminated nature of materials probably indicates a tuff or sediment protolith. Vague textural remnants of coarser clasts-fragmentals are locally preserved(?)

Unique DDH#: 10764 DDH#: 682 P295 File #: DH2951-384

Comments: Cuttings. Soft clayey phyllite (weathered?), with minor blebs of red hematite. Soft enough to be Cretaceous, but larger fragments look phyllitic.

Unique DDH#: 10765 DDH#: 686 P295 File #: DH2951-385

Comments: Cuttings. Soft clayey phyllite (weathered?), with minor blebs of red hematite, and minor greenish chert. Little more iron stained than previous hole (from sulfides??). Soft enough to be Cretaceous, but larger fragments look phyllitic.

Unique DDH#: 15513 DDH#: S-1-55 P295 File #: DH2951-386

Comments: Laminated hematite chert iron formation, with minor porphyroblastic magnetite. Minor hairline veins with red hematite. At least one slip surface (soft sediment??) with beds offset.

Unique DDH#: 15514 DDH#: S503 P295 File #: DH2951-387

Comments: Tuffaceous(?) sericitic phyllite which gets more hematitic before changing to goethite chert iron formation. Red hematitic portion has local limonitic alteration.

Unique DDH#: 15864 DDH#: S505 P295 File #: DH2951-388

Comments: Goethite chert iron formation. Goethite has fine vugs.

Unique DDH#: 15865 DDH#: S506 P295 File #: DH2951-389

Comments: Chert goethite hematite iron formation. Goethite associated with brecciation and carbonate veining.

Unique DDH#: 15866 DDH#: S507 P295 File #: DH2951-390

Comments: Chert goethite iron formation. Goethite is generally disseminated within chert. Local red hematite (alteration? or layers?).

Unique DDH#: 15867 DDH#: S509 P295 File #: DH2951-391

Comments: Chert goethite (and hematite toward base) iron formation with local brecciation and veining with carbonate magnetite alteration and veining.

Unique DDH#: 15868 DDH#: S511 P295 File #: DH2951-392

Comments: Chert grey hematite goethite iron formation. May contain iron silicates an/or Mn oxides(?). Chert contains brittle fractures-veins of oxides.

Unique DDH#: 15905 DDH#: S501 P295 File #: DH2951-393

Comments: Sericitic phyllite (tuffaceous?) that gets red hematitic with depth (and local veinlets with quartz and dark oxides (Mn?)).

Unique DDH#: 15906 DDH#: S502 P295 File #: DH2951-394

Comments: Recrystallized chert with local hematite (and goethite?) with vugs (alteration?).

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 15976 DDH#: H2 P295 File #: DH2951-395

Comments: Chert goethite iron formation with local chert goethite hematite iron formation. Chert goethite locally brecciated near 70-80' (?). Crushed core below 135' had minimal recognizable rock fragments. Crushed core colors are 5R 4/2 (63-68'), 10R 3/6 (68-70, 72-80, 101-110, 130-135, 162-165'), 10R 4/4 (70-72'), 10R 3/4 (80-85, 140-145, 165-177'), 5R 4/4 (85-90, 110-115, 145-150'), 5R 3/6 (90-101'), 5R 3/4 (115-124'), 10R 4/6 (124-130'), 10R 5/2 (135-140'), 5R 5/2 (150-153'), 10R 4/2 (153-160') and 10R 3/2 (160-162').

Unique DDH#: 15977 DDH#: H3 P295 File #: DH2951-396

Comments: Chert goethite hematite iron formation. Minor local brecciation and veinlets with dark hematite or Mn oxides(?). Fragments in crushed core (cuttings?) indicate similar mineralogy, although material is more siliceous/aluminous and less iron rich above 95'. Crushed core colors are 10R 4/2 (66-70, 80-85, 155-160'), 5R 5/2 (70-75, 107-110'), 10R 5/2 (75-80, 160-165'), 10R 4/4 (85-90, 110-120, 145-150'), 5R 5/4 (90-95'), 5R 3/6 (95-100, 120-135'), 5R 4/4 (100-107'), and 10R 3/4 (135-145, 150-155').

Unique DDH#: 15978 DDH#: H4 P295 File #: DH2951-397

Comments: Phyllite with local laminae-thin layers of goethite, chert, hematite, and limonite; over chert goethite limonite hematite iron formation. Oxides replace chert and phyllite locally. Crushed core colors are 10R 3/4 (55-60, 80-85, 131-135'), 5R 5/2 (60-65, 75-80, 85-90, 95-100, 120-125'), 5R 6/2 (65-75'), 10R 5/2 (90-95, 145-150'), 5R 3/4 (100-105, 115-120, 130-131'), 5R 3/6 (105-110'), 5R 2/4 (110-115, 125-130, 135-140'), and 10R 3/6 (140-145').

Unique DDH#: 15979 DDH#: H5 P295 File #: DH2951-398

Comments: Chert goethite hematite iron formation. Local brecciation-fragmentation. All crushed core appears to be fairly iron rich. Crushed core colors are 5R 2/4 (59-65, 85-88'), 5R 3/6 (65-70'), 5R 3/4 (70-80'), 5R 4/4 (80-85'), 10R 3/6 (88-90'), and 10R 4/4 (90-95').

Unique DDH#: 15980 DDH#: H6 P295 File #: DH2951-399

Comments: Chert goethite hematite limonite iron formation with minor phyllite. Local brecciation-fragmentation. Oxide alteration-remobilization is locally calcareous. Uppermost crushed core is less iron rich with some phyllite fragments. Crushed core colors are 5R 6/4 (53-60'), 10R 3/6 (60-65'), 5R 3/4 (65-70, 85-90, 100-110, 115-120'), 10R 4/2 (70-75'), 10R 4/4 (75-80'), 10R 3/4 (80-85, 120-125'), 5R 3/6 (90-100'), and 10R 2/4 (110-115').

Unique DDH#: 15981 DDH#: H12 P295 File #: DH2951-400

Comments: Sericitic phyllite, over the same with grey hematite predominating iron formation, over tuffaceous phyllite with chert (flattened pebbles or attenuated laminae) and goethite. Upper phyllite is kaolinitic(?). Tuffaceous component is intermediate to felsic(?). Only fragments in crushed core above 190'. Crushed core colors are 5R 7/2 (72-90'), 10R 2/4 (90-95, 120-125'), 5R 5/2 (95-100, 155-160, 165-175, 185-190'), 5R 4/2 (100-105'), 5R 3/4 (105-110, 125-130'), 5R 3/2 (110-115'), 10R 3/2 (115-120, 135-140, 150-155, 160-165'), 10R 3/4 (130-135, 140-145'), 10R 4/2 (145-150, 180-185, 190-195'), and 10R 5/2 (175-180'). Variability in crushed core iron content is at least partially due to phyllite and chert. Some Mn oxides and siliceous siltstone or fine sandstone may also be present.

Unique DDH#: 15982 DDH#: H15 P295 File #: DH2951-401

Comments: Phyllite becoming intermixed with chert grey hematite iron formation, with brecciation and quartz veins, which becomes more goethitic with depth. Siliceous siltstone or leached chert is the more prevalent diluter of iron oxides with depth (rather than phyllite). Minor carbonate associated with quartz and hematite alteration. Crushed core colors are 5R 7/2 (77-85, 100-105, 180-185'), 10R 6/2 (85-90'), 5R 6/2 (90-100, 105-110'), 5R 5/4 (110-120'), 5R 4/4 (120-125, 140-150'), 5R 5/2 (125-140, 167-170'), 5R 4/2 (150-155'), 10R 5/2 (155-165, 175-180, 190-195'), 5R 8/2 (170-175'), 10YR 5/2 (185-190'), 10R 4/2 (195-200'), and 5YR 6/2 (200-210'). Core only within 120-130'.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 15983 DDH#: H17 P295 File #: DH2951-402

Comments: Chert, hematite, goethite iron formation with local phyllite. Phyllite varies from being hematitic to somewhat graphitic (150-155'). Minor carbonate associated with quartz and oxide alteration. Brecciation variable, and may be locally mylonitic. Crushed core colors are 10R 3/2 (78-80, 90-92'), 5YR 3/4 (80-84'), 5R 4/4 (84-90'), 10R 3/4 (92-95, 100-102'), 10R 4/4 (95-100, 124-130'), 5R 3/4 (102-105'), 10R 4/2 (105-110, 120-124'), 10R 3/6 (110-120, 145-150'), 5R 5/2 (130-135'), 10R 4/6 (135-140'), 5R 4/2 (140-145'), and 5R 3/6 (150-155').

Unique DDH#: 15984 DDH#: H18 P295 File #: DH2951-403

Comments: Chert, hematite, goethite, limonite iron formation. Alteration may include carbonate, chlorite(?), and quartz along with oxide alteration. Brecciation variable, and may be locally mylonitic. Fractured quartz vein at 145.2' (?) contains a small bleb of native copper (unoxidized surface). Quartz-chert may be locally leached(?). Crushed core colors are 5R 4/4 (73-80, 95-100'), 10R 3/4 (80-85, 90-95, 100-105, 140-145, 150-155'), 5R 3/6 (85-90'), 10R 2/4 (105-115'), 5R 2/4 (115-125, 130-135), 5R 3/4 (125-130, 135-140') and 10R 4/2 (145-150').

Unique DDH#: 15985 DDH#: H19 P295 File #: DH2951-404

Comments: Argillitic chert goethite hematite iron formation. Chert is well fractured to pseudobrecciated with infilling goethite or red hematite. Crushed core colors are 5R 3/4 (60-75'), 10R 3/4 (75-81'), and 5YR 4/4 (81-90').

Unique DDH#: 15986 DDH#: H20 P295 File #: DH2951-405

Comments: Chert goethite hematite iron formation with local minor magnetite. Pyrite cubes are associated with hematitic portions within 75-82'. Crushed core colors are 10R 3/4 (71-75, 154-160'), 10R 3/6 (75-80, 140-145'), 5R 3/4 (82-85'), 10R 4/2 (85-90, 130-140, 150-154'), 10R 4/6 (90-95, 105-110'), 10R 5/2 (95-100, 115-130'), 10YR 7/2 (100-105'), 10R 5/4 (110-115'), and 5R 3/6 (145-150').

Unique DDH#: 15987 DDH#: H21 P295 File #: DH2951-406

Comments: Chert goethite hematite iron formation with local minor limonite over phyllite. Chert is well fractured to brecciated (locally mylonitic?). Phyllite is sericitic to clayey. Carbonate is also present with quartz and iron oxides as alteration. Quartz veins fragments within the crushed core of 70-75'. Crushed core colors are 5YR 3/4 (70-75, 97-100'), 5YR 5/4 (75-80, 91-95'), 10R 3/4 (80-91'), 10R 4/4 (100-105, 110-115, 120-138'), 5R 3/6 (105-110'), 5R 3/4 (115-120'), 10R 4/6 (138-140'), and 10R 5/2 (140-150').

Unique DDH#: 10150 DDH#: PS-2 P295 File #: DH2951-407

Comments: Carbonate, chlorite, quartz, biotite, muscovite phyllitic schist with minor local sulfide graphite chemical sediment in central portion. Contains local sulfide clasts also within 144-203'. Several intrusives cut schists. Previous analyses of the lower one (293-310') indicates an ultramafic (komatiitic) composition. Upper porphyritic one (203-207') may be of similar parentage or perhaps lamprophyric(?). Schist is probably mafic to intermediate volcanics and sediments. Fragmental textures locally visible, and perhaps some pillow rims(?).

Unique DDH#: 10187 DDH#: 56 P295 File #: DH2951-408

Comments: Graphite sulfide phyllite with sulfide veining (marcasite?). Crushed core colors are 5YR 3/4 (103-110'), 10R 3/2 (110-115'), 10YR 3/2 (115-120', N 2 (120-125'), and N 3 (125-130'). The interval 103-110' appears to be goethitic iron formation from crushed core (few fragments).

Unique DDH#: 10351 DDH#: 60 P295 File #: DH2951-409

Comments: The interval 96-99' or so is a quartz feldspar intrusive rock. Could be glacial boulder, but I don't think so. It is quartz plagioclase with a later quartz K-feldspar phase intruding. Core piece with graphite and a small vein with carbonate within intrusive may be out of place. Adjacent iron formation may be recrystallized. Small quartz (and kaolin? from feldspar alteration??) occurs at about 104'. Is intrusive a rare earth contributor(??). Hydrothermal(?) alteration of oxides decreases downward.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 10352 DDH#: 61 P295 File #: DH2951-410

Comments: Magnetite silicate carbonate(?) iron formation. Magnetite variably recrystallized as are greenish silicate blebs (some almost look epidotitic?).

Unique DDH#: 10401 DDH#: 62 P295 File #: DH2951-411

Comments: Magnetite silicate carbonate(?) iron formation. Magnetite variably recrystallized as are greenish silicate blebs (some almost look epidotitic?). Local white quartz and kaolin or carbonate veinlets.

Unique DDH#: 14513 DDH#: AB-22 P295 File #: DH2951-412

Comments: Very fine-grained to aphanitic greenish metabasalt. It is slightly schistose or phyllitic. Has minor brittle fractures veins with minor quartz, carbonate, pyrite, magnetite(?), grey hematite(?) and iron staining. Local thin mylonitic zones (1 cm) with adjacent rock relatively undeformed.

Unique DDH#: 14514 DDH#: AB-23A P295 File #: DH2951-413

Comments: Red hematite, sericite, quartz mylonitic schist. Most of rock is reddish, with local limonitic alteration. Rock is locally very clayey and locally brecciated. Local quartz veins are fractured to brecciated. Original rock type is problematic.

Unique DDH#: 16271 DDH#: S1020 P295 File #: DH2951-414

Comments: Little core. Chert goethite iron formation with much quartz veining and brecciation(?). Original bedding destroyed by tectonism or hydrothermal activity.

Unique DDH#: 16272 DDH#: S1021 P295 File #: DH2951-415

Comments: Folded to brecciated carbonate silicate magnetite iron formation with local veins with goethite , quartz, grey hematite(?), carbonate(?), and pyrite.

Unique DDH#: 16273 DDH#: S1022 P295 File #: DH2951-416

Comments: Chert goethite grey hematite magnetite iron formation. Minor grey hematite towards top and magnetite toward base (both late replacement). Minor structures and quartz veinlets locally.

Unique DDH#: 16274 DDH#: S1023 P295 File #: DH2951-417

Comments: Chert oxide iron formation with magnetite predominating over other oxides (fairly magnetic). Contains folds and scattered shears with slickensides and minor brecciation.

Unique DDH#: 16275 DDH#: S1024 P295 File #: DH2951-418

Comments: Chert oxide iron formation with goethite predominating over other oxides (locally somewhat magnetic). Contains folds and scattered shears with slickensides. Local quartz veins may be internally brecciated.

Unique DDH#: 16276 DDH#: S1025 P295 File #: DH2951-419

Comments: Chert oxide iron formation with grey hematite predominating over minor red hematite alteration(?). Rock is essentially nonmagnetic.

Unique DDH#: 16277 DDH#: S1026 P295 File #: DH2951-420

Comments: Fractured to brecciated chert and goethite iron formation with quartz veining. More goethitic-less cherty toward base.

Unique DDH#: 16278 DDH#: S1027 P295 File #: DH2951-421

Comments: Chert oxide iron formation with goethite predominating over other oxides (locally somewhat magnetic). Contains scattered shears and brecciation.

Unique DDH#: 16279 DDH#: S1028 P295 File #: DH2951-422

Comments: Predominantly oxide chert, variably argillitic iron formation over phyllitic-schistose siltstone. Rock is primarily goethite with lesser hematite and magnetite(?). Rock is calcareous locally, with local shears, folds, brecciation and veinlets. Basal siltstone rock appears to be clastic, but may also contain dolomite.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 16280 DDH#: S1030 P295 File #: DH2951-423

Comments: Argillitic chert oxide iron formation. Oxides vary from goethitic-limonitic to magnetitic-hematitic. Local shears, folds, brecciation and carbonate veinlets. Mn(?) oxides may be hydrothermally replacing the rock locally below 63'.

Unique DDH#: 16281 DDH#: S1031 P295 File #: DH2951-424

Comments: Predominantly chert grey hematite iron formation with minor calcite quartz veins.

Unique DDH#: 16282 DDH#: S1032 P295 File #: DH2951-425

Comments: Carbonate silicate magnetite iron formation with chert (sheared?) at the top and local alteration-oxidation to other iron oxides.

Unique DDH#: 10400 DDH#: S213 P295 File #: DH2951-426

Comments: Very little remaining core. Contains local vugs with drusy quartz.

Unique DDH#: 16114 DDH#: E1001 P295 File #: DH2951-427

Comments: Only crushed core/cuttings samples. Oxide iron formation with relatively little chert. Few fragments in cuttings/crushed core. All samples appear relatively iron rich, with goethite and hematite predominating and minor magnetite. Descriptions are problematic due to sample quality. Crushed core colors are 10R 3/4 (3-20, 25-40, 50-65, 70-75'), 5YR 2/4 (20-25'), 5YR 4/6 (40-45'), 10R 4/4 (45-50'), 10R 3/6 (65-70'), and 10R 2/4 (75-80').

Unique DDH#: 16115 DDH#: E1002 P295 File #: DH2951-428

Comments: Only crushed core/cuttings samples. Relatively iron rich oxide chert iron formation with some phyllite and vein quartz. Upper portion of samples are more goethitic, while the lower portion is more hematitic. Magnetite is scattered. Phyllite may be more prevalent higher up, with vein quartz lower down. Descriptions are problematic due to sample quality. Crushed core colors are 5YR 3/4 (62-70', 80-85, 95-105, 130-140, 150-155'), 10R 4/2 (70-75, 85-90'), 5YR 4/4 (75-80, 90-95'), 10R 3/2 (105-115, 170-175'), 5YR 3/2 (115-120'), 5YR 2/4 (120-130'), 5YR 4/6 (140-145'), 10R 3/4 (145-150, 155-160, 180-190, 195-200'), 5R 3/4 (160-170, 175-180'), and 10R 4/4 (190-195').

Unique DDH#: 16116 DDH#: E1003 P295 File #: DH2951-429

Comments: Only crushed core/cuttings. Samples are generally iron rich oxide iron formation. Upper portion is more magnetite, grey hematite and goethite (with chert?); with the lower portion with less goethite and more hematite. Descriptions are problematic due to sample quality. Crushed core colors are 10R 3/4 (6-15, 130-140, 155-160, 170-180'), 5YR 3/4 (15-40, 45-65, 70-80, 85-95, 115-130, 160-165'), 5YR 2/4 (40-45, 65-70, 80-85, 95-100, 105-110, 165-170'), 5YR 3/2 (100-105, 110-115'), 10R 3/6 (140-145'), 10R 3/2 (145-150'), and 10R 5/6 (150-155').

Unique DDH#: 16113 DDH#: E1000 P295 File #: DH2951-430

Comments: Oxide iron formation with minor chert (predominantly goethite hematite with minor magnetite). Recognizable rock fragments are generally toward the base. Upper thirty feet shows color variation probably due to weathering, with 62-70 and 80-85' being limonitic; 70-80' is hematitic, and 85-90' is a purplish hematite. The interval 95-100' contains quartz vein fragments, some with slickensides. Descriptions are problematic due to the quality of the samples. Crushed core colors are 5YR 4/4 (62-70'), 10R 3/6 (70-75'), 10R 3/4 (75-80, 90-95, 100-105, 155-160'), 5YR 4/6 (80-85'), 5RP 3/2 (85-90'), 10R 4/4 (95-100'), 10R 3/2 (105-110'), 5YR 3/6 (110-150'), and 10R 2/4 (150-155').

Unique DDH#: 16117 DDH#: E1004 P295 File #: DH2951-431

Comments: Only crushed core/cuttings. Oxide chert iron formation (generally iron rich). Predominantly hematite and goethite with minor magnetite. Quartz vein fragments noticeable within 68-75'. Descriptions are problematic due to sample quality. Crushed core colors are 5YR 3/4 (68-75'), 5YR 2/4 (75-85'), 5YR 4/4 (85-95, 110-115'), 10R 3/4 (95-110, 115-150'), and 10R 2/4 (150-155').

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 16585 DDH#: S256 P295 File #: DH2951-432

Comments: Core only in central portion, but recognizable fragments indicate continuation into areas with crushed core. Chert carbonate silicate goethite hematite iron formation. Unit is disrupted, leached, brecciated with irregular textures. Carbonate is fairly abundant. Rock probably results from hydrothermal activity with little indication of the protolith. Crushed core colors are 10R 5/6 (54-60, 90-95'), 10R 5/4 (60-70'), 10R 6/4 (70-75'), 10R 4/6 (75-80'), 10R 4/4 (80-85, 95-100, 155-163'), 10R 5/2 (85-90, 130-135, 144-150'), 5YR 5/4 (100-105, 140-144, 150-155'), 10R 3/6 (105-107'), 5YR 3/6 (107-110, 120-130'), 5YR 3/4 (110-120'), and 5YR 6/2 (135-140'). Material should be extensively sampled. Oxidized pyrite cubes within 80-85'.

Unique DDH#: 16586 DDH#: S257 P295 File #: DH2951-433

Comments: Laminated magnetite, sericitic phyllitic schist, and schistose greywacke (tuffaceous?). Interesting.

Unique DDH#: 16587 DDH#: S258 P295 File #: DH2951-434

Comments: Chert grey hematite goethite iron formation with a trace of carbonate. Chert contains some vugs and leaching. Fe oxides may be replacing chert locally. "Chert" may be silicified clastic rock, with oxides being clasts (see Unique 16588). Recrystallization makes identification difficult.

Unique DDH#: 16588 DDH#: S260 P295 File #: DH2951-435

Comments: Quartz sericite goethite red hematite schist over chert goethite hematite iron formation or silicified greywacke with oxide clasts (hematite-goethite). Larger oxide clasts are present near the base. Siliceous grains are locally observable in the "chert". Uppermost schist may be mylonitic or tuffaceous.

Unique DDH#: 16589 DDH#: S261 P295 File #: DH2951-436

Comments: Little core remains. Chert goethite hematite iron formation or silicified greywacke with oxide clasts (hematite-goethite). Siliceous grains are locally observable in the "chert". Recrystallization makes quartz relationships difficult to determine.

Unique DDH#: 16590 DDH#: S263 P295 File #: DH2951-437

Comments: Chert goethite hematite iron formation or silicified greywacke with oxide clasts (hematite-goethite). Siliceous grains are locally observable in the "chert". Recrystallization makes quartz relationships difficult to determine. Later limonitic-goethitic alteration also occurs.

Unique DDH#: 16591 DDH#: S266 P295 File #: DH2951-438

Comments: Carbonate biotite quartz plagioclase goethite schist. Probably igneous and be tuffaceous. Contains local deformed plagioclase(?) phenocrysts(?)

Unique DDH#: 16634 DDH#: S327 P295 File #: DH2951-439

Comments: Carbonate, silicate, magnetite iron formation with minor chert and sulfide chemical sediment. Predominantly iron silicates. Most pyrite is associated with cross-cutting veins-shears, as is carbonate and hematite. Unit gets vuggy toward base. Local minor clay - epidote alteration.

Unique DDH#: 16635 DDH#: S328 P295 File #: DH2951-440

Comments: Oxide chert iron formation. Oxide is predominantly goethite and grey hematite. Unit with much brecciation and replacement of chert by oxides. Brecciation may be from collapse (karst), hydrothermal alteration, or tectonism.

Unique DDH#: 16641 DDH#: S331 P295 File #: DH2951-441

Comments: Oxide "chert" iron formation. Oxide is predominantly goethite and grey hematite. Unit with replacement of "chert" by oxides. Chert may be silicified quartz clastic rock (greywacke or arenite??).

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 16643 DDH#: S332 P295 File #: DH2951-442

Comments: Oxide "chert" iron formation. Oxide is predominantly goethite and grey hematite. Unit with replacement of "chert" by oxides. Chert may be silicified quartz clastic rock (greywacke or arenite??).

Unique DDH#: 16645 DDH#: S333 P295 File #: DH2951-443

Comments: Oxide chert iron formation. Oxide is predominantly goethite. Contains very little chert. Local brecciation may be tectonic or related to alteration or solution collapse.

Unique DDH#: 16647 DDH#: S334 P295 File #: DH2951-444

Comments: Oxide chert silicate(?) iron formation. Oxide is predominantly goethite with lesser grey hematite and magnetite. Contains relatively little chert. Dark color makes iron silicates difficult to discern, but density indicates rock is not that oxide rich locally.

Unique DDH#: 15648 DDH#: E1006 P295 File #: DH2951-445

Comments: Only crushed core samples. Oxide chert iron formation, with all samples relatively iron rich although there are some density differences. Oxides appear to be largely goethite and grey hematite with minor magnetite. Crushed core colors are 10R 3/4 (2-20, 25-30, 50-55, 145-150, 165-175, 185-190, 195-200'), 5R 3/4 (20-25'), 10R 3/6 (30-50, 55-90, 105-120, 125-145, 150-160, 175-180'), 10R 4/4 (90-105, 120-125'), 5YR 3/4 (160-165'), 10R 3/2 (180-185') and 5YR 4/4 (190-195').

Unique DDH#: 15644 DDH#: E1005 P295 File #: DH2951-446

Comments: Only crushed core samples. Oxide chert iron formation with predominantly goethite grey hematite. There is some density variation however (could be related to size of crushing?). Crushed core colors are 5YR 3/4 (3-10, 30-40, 55-60, 65-70, 85-95, 115-120'), 5YR 4/2 (10-20'), 5YR 4/4 (20-30, 100-105, 110-115'), 5YR 3/6 (45-55'), 5YR 2/4 (60-65, 70-85'), 10R 3/2 (135-145'), and 10R 3/4 (145-150').

Unique DDH#: 16621 DDH#: S313 P295 File #: DH2951-447

Comments: Goethite chert iron formation. No bedding with either brecciation or thorough replacement (by goethite) and solution collapse of chert.

Unique DDH#: 16622 DDH#: S315 P295 File #: DH2951-448

Comments: Carbonate silicate magnetite sulfide iron formation. Local melanterite alteration of sulfides. Local goethite and grey hematite of magnetite locally. Contains just a trace of chert. Compared with other iron formations of this type, the carbonate component predominates.

Unique DDH#: 16623 DDH#: S316 P295 File #: DH2951-449

Comments: Chert goethite hematite iron formation. Local disruption or hydrothermal brecciation as oxides replace chert. Locally has carbonate and is vuggy.

Unique DDH#: 16624 DDH#: S317 P295 File #: DH2951-450

Comments: Core may be partially scrambled with unique 16625. Goethite chert hematite iron formation over carbonate silicate magnetite iron formation with hematitic or goethitic intervals (alteration??). Upper goethitic portion may be from weathering. Local epidote, chlorite or light green amphibole alteration, usually associated with local fragmentation.

Unique DDH#: 16625 DDH#: S318 P295 File #: DH2951-451

Comments: Core may be partially scrambled with unique 16624. Locally brecciated (with goethite alteration) chert hematite magnetite iron formation over goethite limonite chert iron formation over magnetite silicate carbonate iron formation with pyrite veinlets. Pyrite veinlets also contain iron carbonate, quartz and grey hematite or magnetite.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 16702 DDH#: S368 P295 File #: DH2951-452

Comments: Chert goethite hematite iron formation. Oxides with calcite replace the chert (good textural relationships). Small hematitic interval may be argillitic. "Chert" within 120-125' may be a silicified tuff. Appears to contain some sericite. Recrystallization makes identity uncertain.

Unique DDH#: 16703 DDH#: S369 P295 File #: DH2951-453

Comments: Magnetite chert iron formation over goethite chert iron formation. Goethite replacing magnetite(?).

Unique DDH#: 16706 DDH#: S370 P295 File #: DH2951-454

Comments: Believed to be predominantly silicate iron formation that is altered and cut by veins. Local accumulations (vein associated or more primary??) with grey hematite, graphite and Mn oxides. This includes an extremely brecciated quartz vein or chert bed within 170-175'. Core is topped by a goethitic unit (due to surficial weathering). Definitely analyze.

Unique DDH#: 16707 DDH#: S371 P295 File #: DH2951-455

Comments: Laminated magnetite chert iron formation with alternating alteration to goethite or hematite. Rock is calcareous, but whether this is related to alteration, or is more primary is uncertain.

Unique DDH#: 16708 DDH#: S372 P295 File #: DH2951-456

Comments: Chert hematite goethite iron formation, with oxides replacing fragmental chert. Local limonitic altered more argillaceous portions.

Unique DDH#: 16709 DDH#: S374 P295 File #: DH2951-457

Comments: Chert goethite iron formation with minor carbonate veinlets.

Unique DDH#: 16343 DDH#: S1000 P295 File #: DH2951-458

Comments: Carbonate silicate magnetite iron formation with scattered veinlets with quartz carbonate goethite and grey hematite or magnetite.

Unique DDH#: 16344 DDH#: S1001 P295 File #: DH2951-459

Comments: Laminated chert magnetite iron formation with local brecciation of chert. Minor alteration to hematite occurs locally.

Unique DDH#: 16346 DDH#: S1002 P295 File #: DH2951-460

Comments: Laminated chert magnetite iron formation with local brecciation of chert. Alteration to goethite and hematite occurs locally, especially near the top. More goethitic portions often have secondary magnetite developed.

Unique DDH#: 16348 DDH#: S1003 P295 File #: DH2951-461

Comments: Goethite chert over laminated chert magnetite iron formation with local brecciation of chert. Alteration to goethite and hematite occurs locally to magnetite. Upper goethitic portion is probably from surficial weathering. More goethitic portions often have secondary magnetite developed.

Unique DDH#: 16350 DDH#: S1004 P295 File #: DH2951-462

Comments: Chert silicate carbonate magnetite iron formation. Chert is folded and brecciated (mylonitic?). Unit contains little magnetite.

Unique DDH#: 16351 DDH#: S1005 P295 File #: DH2951-463

Comments: Chert with goethitic and hematitic alteration.

Unique DDH#: 15653 DDH#: S1007 P295 File #: DH2951-464

Comments: Chert goethite hematite magnetite iron formation. Relatively little magnetite left. Generally more hematitic and less goethitic downhole.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 15656 DDH#: S1008 P295 File #: DH2951-465

Comments: Goethite chert iron formation over red hematitic phyllitic iron formation over chert. Vugs in goethite occasionally have kaolin. Hematitic phyllite presumed fault related.

Unique DDH#: 15659 DDH#: S1009 P295 File #: DH2951-466

Comments: Chert goethite limonite iron formation with vugs. Looks hydrothermally(?) altered.

Unique DDH#: 16357 DDH#: S1011 P295 File #: DH2951-467

Comments: Chert magnetite iron formation with variable goethitic alteration. Locally argillitic and mylonitic(?).

Unique DDH#: 15669 DDH#: S1013 P295 File #: DH2951-468

Comments: Chert magnetite iron formation with brecciation and large (several feet) quartz veins with associated goethite alteration. Veins have minor vugs with grey hematite crystals.

Unique DDH#: 15673 DDH#: S1014 P295 File #: DH2951-469

Comments: Carbonate silicate sulfide magnetite iron formation. Locally deformed to brecciated. Minor quartz veining or recrystallized chert. Definitely sample.

Unique DDH#: 16359 DDH#: S1012 P295 File #: DH2951-470

Comments: Goethite iron formation over phyllitic hematite goethite (mylonitic) and chert. Latter part may also have silicate iron formation. Little core remains.

Unique DDH#: 16361 DDH#: S1015 P295 File #: DH2951-471

Comments: Chert goethite iron formation with local brecciation.

Unique DDH#: 16363 DDH#: S1016 P295 File #: DH2951-472

Comments: Laminated chert magnetite iron formation over goethitic iron formation. Magnetite portion locally altered to grey hematite. Goethite has carbonate veinlets.

Unique DDH#: 16365 DDH#: S1017 P295 File #: DH2951-473

Comments: Chert goethite iron formation with brecciation, vugs, and carbonate. Quartz veinlets have scattered pyrite cubes.

Unique DDH#: 16368 DDH#: S1019 P295 File #: DH2951-474

Comments: Chert brecciated and replaced by goethite, limonite and lesser hematite. Nor core in central portion.

Unique DDH#: 14499 DDH#: AB-25 P295 File #: DH2951-475

Comments: Grey, slightly graphitic phyllite. No sulfides except for disseminated chalcopyrite (trace). Small fault zone with brecciation and gouge.

Unique DDH#: 14498 DDH#: AB-8 P295 File #: DH2951-476

Comments: Chloritic sericitic phyllitic schist with local quartz veins (some brecciated during the continuing deformation?). Flattened clasts (volcaniclasts?) occur locally. Local smeared out pyrite may have been primary.

Unique DDH#: 14504 DDH#: AB-2 P295 File #: DH2951-477

Comments: Black-dark grey graphitic sulfide phyllite (schist?). Some pyrite is stratiform, while other pyrite is more secondary (remobilized?). Some pyrite is very pale colored.

Unique DDH#: 16404 DDH#: S1036 P295 File #: DH2951-478

Comments: Relatively massive magnetite and grey hematite(?) iron formation. Minor thin veinlets with quartz or calcite. Some of this quartz could be thin recrystallized chert laminae.

Appendix 295-G. DRILL LOG COMMENT FIELD

Unique DDH#: 16406 DDH#: S1037 P295 File #: DH2951-479

Comments: Chert goethite iron formation (brecciated or pseudobrecciated); over limonitic iron formation; over goethite(?) silicate iron formation with Mn oxides(?), and a trace of malachite along fractures; over vuggy goethitic iron formation; over siliceous fine sandstone or siltstone undergoing replacement by goethite. Definitely sample.

Unique DDH#: 16408 DDH#: S1038 P295 File #: DH2951-480

Comments: Carbonate chert silicate magnetite iron formation. Perhaps slightly higher metamorphic grade than normal, with needles of several varieties of amphibole and abundant porphyroblastic (secondary) magnetite. Good strain slip cleavage present locally. Local shearing.

Unique DDH#: 16410 DDH#: S1039 P295 File #: DH2951-481

Comments: Carbonate silicate magnetite iron formation. Perhaps slightly higher metamorphic grade than normal, with needles of several varieties of amphibole. Porphyroblastic (secondary) magnetite is lacking is not as ubiquitous as in unique 16408. Local shearing.

Unique DDH#: 16417 DDH#: S1041 P295 File #: DH2951-482

Comments: Little core remaining. Goethitic silicate iron formation probably derived from carbonate silicate magnetite(?) iron formation.

Unique DDH#: 16418 DDH#: S1042 P295 File #: DH2951-483

Comments: Little core remaining. Carbonate silicate iron formation. Shear at 206' contain actinolite(?), pyrite, and goethitic alteration (with carbonate).

Unique DDH#: 16419 DDH#: S1043 P295 File #: DH2951-484

Comments: Chert hematite iron formation with local brecciation and Mn oxide(?) veining. Some "chert" is probably clastic siliceous sediment.

Unique DDH#: 16109 DDH#: S1044 P295 File #: DH2951-485

Comments: Chert hematite magnetite silicate iron formation with local brecciation and flattening of fragments. Some "chert" is probably clastic siliceous sediment.

Appendix 295-K: Thin Section Summary and Tables

June 15, 1993

For the Department of Natural Resources

By

James L. Welsh

Gustavus Adolphus College

Introduction

This report supplements the geological investigations of Project #278 of the Minnesota Department of Natural Resources--Hibbing. The purpose of the petrographic work was to augment the extensive diamond drill hole core relogging program. Specific goals include identification of primary rock textures and lithologies, protoliths of the metamorphic rocks, and characterization of alteration.

This report is divided into three sections. The first section (Appendix 295-G) contains a summary of the major features identified in the thin sections. The second (Appendix 295-G) summarizes these data into two tables: one concerning lithology, protolith, metamorphic grade, and alteration; the other concerning mineralogy. The third section (Appendix 295-H) provides descriptions of each thin section examined.

I. Summary of Results

Lithologies

The rocks described in the petrographic work can be divided into the following groupings:

1. Iron formation, oxidized and unoxidized
2. Clastic and calcareous metasedimentary rocks
3. Mafic metavolcanic rocks (including amphibolites)
4. Mafic intrusive rocks
5. Fragmental and felsic metavolcanic rocks
6. Felsic to intermediate intrusive rocks

Iron Formation and Related Rocks

A large number of sections examined fall into this category and include both oxidized and unoxidized varieties. Unoxidized varieties typically contain quartz (recrystallized chert) and iron silicates such as stilpnomelane and minnesotaite. Included here are a number of conglomeratic specimens, which appear to contain intraclasts of chert in a matrix containing iron-silicates (#'s 272-277, 279, 281). Iron silicates are partially to totally replaced by hematite and/or limonite in the oxidized varieties. In general these rocks are not highly metamorphosed. Oxidation in these samples postdates metamorphism. A significant number of these sections contain small amounts of (secondary?) carbonate.

Clastic Metasedimentary Rocks and Marbles

Most of these rocks are quartz-rich, sericitic phyllites and fine-grained schists which were originally siltstones and fine-grained sandstones. Many of these are bedded or laminated, and a couple of specimens appear to be graded. A number of these samples show significant replacement by hematite, possibly indicating proximity to iron formation. Small amounts of secondary carbonate are common. Marbles are relatively uncommon, and are typically micaceous.

Mafic Metavolcanic Rocks

Mafic metavolcanic rocks are relatively uncommon in this suite. Included here are amphibolitic rocks of basaltic to andesitic composition, and are identified as such on the basis of texture and mineralogy. In relatively low grade specimens plagioclase typically shows a relict felty texture. A few specimens are porphyritic. Typical minerals in these rocks include hornblende or actinolitic hornblende, biotite, and chlorite, with secondary epidote and sphene.

Mafic Intrusive Rocks

Fine- to medium grained metagabbros (or -diorites?) and metadiabase constitute another grouping of rocks in this suite. These rocks are typified by a relict ophitic or diabasic texture, 50-70% original plagioclase, and 3-5% Fe-Ti-oxides (probably ilmenite) which have been altered to leucoxene. Original mafic minerals have been replaced by hornblende or actinolitic hornblende. These rocks for the most part do not contain a deformational fabric, but have been metamorphosed to upper greenschist or lower amphibolite facies. One unique sample (#026) is a hornblende pyroxenite. The mineralogy of this rock is probably primary and consists of pyroxene grains surrounded by large poikilitic hornblende (some recrystallization of hornblende is evident, however).

Fragmental and Felsic Metavolcanic Rocks

A few specimens in this study are pyroclastic (or perhaps tuffaceous metasediments). All samples have been sufficiently sericitized or chloritized to mask the primary texture. Only sample #030 was probably originally a dacitic flow (or shallow intrusive). These rocks appear to range in composition from dacite to andesite. Specimen #101 may have been originally trachytic.

Felsic to Intermediate Intrusive Rocks

Six thin sections of rocks fitting this description were examined. Of particular interest is the timing of intrusion with respect to regional metamorphism and deformation. Two specimens of metagranite (#003, 005) have undergone shearing and metamorphism. A well developed foliation has developed along shear bands. That foliation has been slightly crenulated in spec. #005, indicating two possible periods of deformation.

Specimen #023 is a tonalite. Plagioclase in this rock has been heavily sericitized, and epidote is well developed. There appears to have been little textural modification. This rock has undergone a thermal event, but does not appear to have been deformed.

Specimens 036, 038, and 040 appear to be related. They are monzodioritic to dioritic in composition. Specimens 36 and 38 have undergone a thermal event. Plagioclase is moderately to heavily sausserized. Quartz shows some strain, and there may have been some grain boundary modification. Specimen 40 exhibits foliation of biotite and hornblende, but it is not clear whether this foliation is primary or secondary. Quartz and feldspar appear to have undergone some recrystallization, however. Plagioclase in this rock is relatively fresh.

Metamorphism and Deformation

Rocks in this study have not been highly metamorphosed. Metamorphism for the most part ranges from lower greenschist facies to lower amphibolite facies.

The metavolcanic and metasedimentary rocks generally show some evidence of deformational fabric. Specimens #3, 17, 20, 83 show evidence of two deformations. Some of the iron formations show development of a distinct foliation or cleavage as well, but many do not. As a whole the mafic intrusive rocks do not possess a fabric, however they have clearly been metamorphosed. It is unclear whether these rocks were intruded late with respect to deformation, or whether these rocks were merely more strain resistant.

A few specimens have undergone shear. Specimens 3 and 5 contain well developed shear bands, and specimens 42, 44, and CCW17456,57 are phyllonites.

Alteration

Unless alteration is unusual, it is difficult to determine from the examination of a single specimen the nature of the "alteration". Low-grade hydrothermal metamorphism may be indistinguishable from greenschist facies metamorphism, for example. Preferably it helps to have altered and "unaltered" rocks for comparison. Most of the specimens selected for study show some degree of alteration.

The most common alteration in these rocks is the development of ferric oxides and hydroxides in the iron formations. In some cases these oxides have been mobilized, so that clastic sediments, probably nearby in the stratigraphic sequence, have been altered by replacement. A few hematitic and goethitic specimens have high Mn contents, notably specimens 11, 12, 13, and 55, 56, 57. An Mn-oxide (pyrolusite?) was identified in reflected light in specimen 13. Mn-oxide minerals were not identified in the other sections. Specimens 76 and 78 also have relatively high Mn contents. These contain a pink carbonate mineral, possibly rhodochrosite. Sample 105 is also manganiferous. This sample contains 20% fine carbonate; perhaps this is rhodochrosite as well.

Specimen 34 contains thin veins of what appear to be anhydrite and possibly apophyllite. Introduction of calcium is indicated by presence of diopside and epidote in association with these veins.

A number of specimens are partially kaolinized. These specimens include #'s 46, 95, 182, and 187. Of special note is abundant chlorite associated with specimen 95. None of these is associated with sulfide, however.

Specimens 95 and 103 have high MgO values. Both samples are metasediments and contain abundant chlorite.

Simple metamorphism (with hydration) can account for such common secondary minerals as sericite, chlorite, epidote, sphene. Without accompanying sulfidation or elevated values of key trace elements, it is unlikely that these assemblages are a result of hydrothermal alteration. Carbonate minerals are also common secondary minerals in these rocks.

Economic Geology

Disregarding the iron formations, samples of interest are those mentioned in the previous section. High Mn values are present in samples 11, 12, 13, 76, 78, and 105. Of particular interest are the probable presence of Mn-bearing carbonates in samples 76, 78, and 105.

Specimens 95 and 103 have high MgO values. As Mg-enrichment is associated with the base of massive sulfide deposits, these samples might merit further study. However, sulfides are lacking in these sections.

Specimen 34 shows an interesting calcic alteration, with possible anhydrite and apophyllite. A chemical analysis was not provided for this sample, however.

Specimen 7 contains sulfide-rich veins. This specimen also shows slightly elevated arsenic and mercury values.

III. Tabular Studies

Explanation of Abbreviations

Grain Size

| | | |
|---|-----------|------------|
| 1 | Very Fine | <0.2 mm |
| 2 | Fine | 0.2-1.0 mm |

Appendix 295-L: Thin Section Descriptions

June 15, 1993

For the Department of Natural Resources

By

James L. Welsh

Gustavus Adolphus College

Spec. No: 295000001

Chip Desc: green/black med. grained, biot-hb schist w/ thin marble layers

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| biotite | 30 | brown; lepidoblastic |
| hornblende | 15 | blue green; porphyroblastic; intergrown w/ biot. |
| quartz | 30 | fine; granoblastic |
| carbonate | 15 | ankerite?; alters slightly to Fe-stain; doesn't fizz readily; intergrown & in equil w/ bi-hb-qz |
| plagioclase | <5 | slightly alt. to ser. |
| epidote | 1 | intergrown-in equil. w/ biot. |
| opaques | 1 | mostly magnetite; trace py and cp |

Structures/Textures: foliated, banded; some biot. wraps around hb; looks as if hb is slightly rotated. mineral growth appears synkinematic.

Alteration: very slight sericitization of plag; minor alt. of hb to fibrous biot.

Interpretation: protolith: volcaniclastic (intermediate)? with intercalated carbonate; foliation possibly developed by shearing, then recrystallized. Marble interlayers suggest primary calcareous intercalation, with possible mobilization of carbonate into amphibolite matrix during metamorphism. Assemblage: biot-hb-carb-qz-ep: Amphibolite facies.

Spec. No: 295000002

Chip Desc: med.-grained, banded biot-amphibolite w/ somewhat diffuse marble interlayers

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| hornblende | 60 | pale bluish green; poikiloblastic |
| calcite | 20 | anhedral to subhedral; appears to partially replace hb; could be introduced |
| quartz | 10 | small, mostly as inclusions in hb and calcite; couple of bands rich in qz |
| biotite | 3 | one band in corner of slide |
| epidote | 1 | |
| sphene | .5 | |
| apatite | .1 | |
| sericite | 5 | |

Structures/Textures: appears to be banded; grain size bimodal: mostly med. grn hb,cc, w/ v. fine granoblastic quartz. Much of hb is poikiloblastic

Alteration: sericite-replaces plag? (note: plag not observed). Much of carbonate may be introduced.

Interpretation: protolith: volcaniclastic (intermediate)? with intercalated carbonate; amphibolite facies. Marble interlayers suggest primary calcareous intercalation, with possible mobilization of carbonate into amphibolite matrix during metamorphism

Spec. No: 295000003

Chip Desc: med. grained, foliated, possibly cataclastic, porphyritic granite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| microcline | 35 | larger "porphyroclasts", somewhat poikilitic, perthitic (perthite plagioclase mostly replaced by musc); smaller polygonal grains in matrix |
| quartz | 30 | mostly smaller polygonal grains |
| plagioclase | 20 | ragged, sericitized, mostly replaced |
| biotite | 5 | lepidoblastic; olive brown |
| muscovite | 10 | lepidoblastic; forms spaced folia; some as sericite |
| apatite | tr | |
| chlorite | .5 | minor alt. of biotite |

Structures/Textures: Originally porphyritic with microcline phenocrysts. Present texture metamorphic: phenocrysts now porphyroclasts with partially polygonized matrix. Spaced foliation defined by lepidoblastic muscovite and biotite, slightly crenulated.

Alteration: plagioclase moderately altered to sericite/musc.

Interpretation: Protolith: plutonic igneous--porphyritic granite. Development of spaced foliation, probably by shear, with subsequent recrystallization probably at amphibolite grade. Foliation slightly crenulated suggesting 2 deformations. Muscovite developed metamorphically--from earlier sericitization of plagioclase.

Spec. No: 2951000004

Chip Desc: fine-med. biotite calcite schist

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---------------------------------------|
| biotite | 40 | olive green, lepidoblastic (somewhat) |
| calcite | 30 | granoblastic to decussate, untwinned |
| quartz | 20 | small, granoblastic grains |
| epidote | 10 | |
| apatite | tr. | |
| magnetite | tr. | |

Structures/Textures: biotite somewhat lepidoblastic defining a weak foliation

Alteration: none

Interpretation: Protolith: calcareous (volcaniclastic?) metasediment? Quartz grains look clastic. Assemblage: biotite-calcite-quartz-epidote. Amphibolite grade.

Spec. No: 295000005

Chip Desc: med. grained, dark granitoid w/ reddish fspr

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 40 | polygonal, mostly small matrix grains; outlines of larger original grains visible |
| plagioclase | 20 | generally sericitized, a few partially recrystallized porphyroclasts |
| microcline | 25 | mostly small, polygonal, some partially recrystallized porphyroclasts |
| biotite | 8 | olive green |
| muscovite | 5 | |
| magnetite | 1 | |
| pyrite | 1 | |
| chlorite | <1 | replaces biotite |

Structures/Textures: foliated, polygonized, porphyroclastic; some wrapping of biot-musc folia around porphyroclasts

Alteration: plаг lightly sericitized; minor replacement of biot by chl

Interpretation: Protolith: plutonic igneous (granite). Cataclasized, recrystallized to smaller grain size.

Spec. No: 295000007

Chip Desc: pyrite-filled fractures in iron oxide + quartz host (iron formation?)

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| pyrite | 40 | fill anastomozing fractures |
| quartz | 25 | some very fine, "cherty". Some coarser vein qz |
| magnetite | 15 | v. fine, disseminated; assoc. w/ chert |
| hematite | 15 | secondary, replacing mt; two generations: finely crystalline and later cryptocrystalline |
| limonite | 5 | late, cryptocrystalline |
| pyrrhotite? | tr | creamy in reflected light; strong anisotropism |

Structures/Textures: subparallel, in part anastomozing, fractures filled with pyrite cuts across what appears to be a fine lamination between quartz and v. fine magnetite, probably indicating a primary layering.

Alteration: hematite from primary magnetite; later cryptocrystalline hematite and limonite.

Interpretation: Probably fractured, altered iron formation. Fractures later filled with pyrite. First stage of alteration, of magnetite to finely crystalline hematite predates fracturing. Later cryptocrystalline hematite and limonite postdate pyrite.

Additional Comments: Magnetic character of chip probably due to presence of fine magnetite

Spec. No: 2951000008

Chip Desc: hematite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| hematite | 70 | finely crystalline and later cryptocrystalline |
| limonite | 10 | cryptocrystalline alteration product |
| magnetite | 1 | remnants |
| quartz | 19 | finely crystalline, visible in reflected light, not visible in transmitted light due to opacity of hematite |

Structures/Textures: some thin, subparallel bands of coarser, more reflective hematite; remainder is very fine cryptocrystalline hematite and limonite. A few remnants of primary magnetite

Alteration: limonite replacing hematite

Interpretation: hematite probably derived from oxidation of primary magnetite

Spec. No: 2951000009

Chip Desc: iron formation

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 30 | mostly very fine-grained; also as larger polycrystalline granules |
| hematite | 45 | replaces primary magnetite |
| magnetite | 10 | relic cores in hematite |
| pyrite | 10 | intergrown with hematite, especially along cleavage; generally confined to specific layers |
| limonite | 5 | |

Structures/Textures: primary laminations of alternating fine-quartz and iron oxide or pyrite; layers have been folded, with development of axial plane clvg; granules of silica are flattened in plane of foliation; some late stage veining of later (remobilized?) hematite and minor pyrite

Alteration: Primary magnetite mostly replaced by hematite. Later replacement of hematite by cryptocrystalline hematite and limonite veins. Pyrite remobilized along cleavage planes and in late veins

Interpretation: magnetite-bearing iron formation, with magnetite later replaced by hematite. Later folding developed cleavage, along which pyrite is developed. Pyrite possibly primary, but some pyrite is remobilized.

Spec. No: 2951000011

Chip Desc: granular ("cherty") iron formation; chip subdivided into hematite-rich layer and quartz-rich layer

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 70 | v.fine, microcrystalline to crystalline |
| magnetite | | relict cores, replaced by hematite |
| hematite | 30 | replaces magnetite, later cryptocrystalline hem. replacing earlier hem |

Structures/Textures: probable primary layering indicated by quartz-rich and hematite-rich areas; weak foliation at high angle to layering, marked by remobilized hem. and "streakiness" in "chert".

Alteration: oxidation of primary magnetite to hematite; later cryptocrystalline hematite replacing earlier hematite

Interpretation: Deformed banded iron formation, probably Proterozoic, with deformation producing weak secondary foliation cutting across primary layering. Hematite replacing primary magnetite. Original chert recrystallized to v. fine-grained quartz.

Spec. No: 2951-012

Chip Desc: granular ("cherty") iron formation, chip cuts across hematite-rich layer and silica-rich layer

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|----------------------------|
| quartz | 70 | v. fine-grained |
| hematite | 30 | replaces primary magnetite |
| magnetite | | relict cores |

Structures/Textures: primary layering intersected at high angle by weak secondary foliation, marked mostly by hematite

Alteration: hematite replacing primary magnetite; late cryptocrystalline hematite replacing crystalline hem.

Interpretation: Deformed banded iron formation, probably Proterozoic, with deformation producing weak secondary foliation cutting across primary layering. Hematite replacing primary magnetite. Original chert recrystallized to v. fine-grained quartz.

Additional Comments: There is a "dustiness" to the chert. Some is v. fine hem. Low K and Na values in chem analysis suggest feldspars are absent, thus not likely that this is a fspr alt. It is therefore not likely that the chert is tuffaceous.

Spec. No: 2951000013

Chip Desc: fractured quartz-calcite vein?

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 65 | anhedral, strained, partially polygonized and sutured |
| calcite | 630 | anhedral, ragged, secondary as fracture fillings (and replacements?) |
| apatite | 1 | small hex. crystals with sector zoning, occurs only as inclusions in calcite |
| Mn-oxide | 4 | pyrolusite?; larger anhedral grain; locally patchy; also fills in cracks |

Structures/Textures: fractured--cataclasized? Quartz partially polygonized with sutured boundaries
Veins filled with calcite and Mn-oxide.

Alteration: secondary carbonate replaces feldspars?, fills in cracks. Mn-oxide also introduced.

Interpretation: Protolith: quartz vein?. Deformed, partially recrystallized. Subsequently fractured with introduction of calcite and Mn-oxide. Lack of twinning in calcite indicates vein-filling postdates deformation.

Spec. No: 2951000017

Chip Desc: crenulated phyllite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| micas | 70 | intergrowth of v. fine grained biotite, muscovite, chlorite |
| quartz | 25 | (+ fspr?) v. fine grained |
| hematite | 5 | v. fine, disseminated, probably after magnetite |
| tourmaline | tr. | |

Structures/Textures: crenulated foliation with development of spaced S₂ along axial planes of crenulation

Alteration: hematite, probably after magnetite

Interpretation: metapelitic; two deformations

Spec. No: 2951000019

Chip Desc: lt. grey v. fine quartzite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 75 | recrystallized, somewhat polygonal |
| sericite | 23 | |
| opakes | 2 | prob mostly v. finely dissem. hematite, prob altering from magnetite |

Structures/Textures: very fine grained; sericite defines a weak foliation

Alteration:

Interpretation: fine-grained metasiltstone--tuffaceous?; metamorphosed--greenschist grade; sericite probably developed after fsprs or clays

Spec. No: 2951000020

Chip Desc: lt. reddish brown v. fine-grained semischist

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| muscovite | 69 | v. fine grained (sericite) |
| quartz | 30 | (+ fspr?) |
| hematite | 1 | ? v. fine, disseminated, also forms a couple of thin seams; secondary |
| tourmaline | | tr |

Structures/Textures: primary layering defined by slight change in grain size. S_1 foliation parallel S_0 . Weak crenulation with weak S_2 axial pl. foliation, defined by ms., developed oblique to S_0 . Fine, conjugate and en echelon fractures filled w/ hematite.

Alteration: hematite appears secondary

Interpretation: protolith: siltstone-shale. Two metamorphic/deformational events.

Spec. No: 2951000022

Chip Desc: dark green to black, fine-med. grained metagabbro

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| plagioclase | 34 | long laths; heavily sausseritized esp. cores.; rims albitic or poss. Kfspr (R.I. < qz). (orig. 60%) |
| quartz | 2 | interstitial |
| augite | 2 | relict cores of hb/act. grains |
| hornblende | 13 | blue green pleo.--generally outer edges of orig. mafic grains |
| actinolite | 12 | brown, weakly pleo., fibrous, radial mats; replaces hornblende and augite, typically occurs in cores of hb grains |
| chlorite | 10 | replaces amphiboles |
| biotite | 2 | intergrown with chlorite |
| epidote | 20 | abundant; secondary, result of sauss. |
| ilmenite | 2 | skeletal, mostly altered to sphene + biotite (orig. 5%) |
| sphene | 3 | secondary, after ilmenite |
| pyrite | tr | altering to hem |

Structures/Textures:

Alteration: plagi heavily sausseritized; actinolite replaces hb + augite ; chlorite replaces hb +(biot?); ilmenite replaced by sphene; pyrite (minor) altering to hem.

Interpretation: Protolith: gabbro (or diabase), possibly diorite. Secondary mineralization probably result of greenschist grade metamorphism. It's also possible that hornblende formed deuterically, with later metamorphism producing the actinolite-chlorite-epidote-sphene assemblage.

Spec. No: 295000023

Chip Desc: pinkish, med. grained, hb tonalite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| plagioclase | 60 | mod. to heavily sericitized; some zoning |
| quartz | 20 | anhedral, intersitial |
| hornblende | 10 | bluish green, pleo. |
| biotite | 2 | |
| chlorite | 3 | replacing biotite |
| epidote | 5 | yellow, euhedral to subhedral grains |
| magnetite | <1 | partially replaced by hem. |

Structures/Textures:

Alteration: mod to heavy sericitization of plag; chlorite replacing biotite; secondary epidote

Interpretation: protolith: tonalite. Moderately altered.

Additional Comments: pinkish color in chip suggests presence of K-fspr, but K-fspr is not evident in thin section.

Spec. No: 2951000024

Chip Desc: Fe-oxide vein in quartz

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 57 | |
| hematite/ | 40 | cryptocrystalline; vein and fracture filling in quartz |
| limonite | | |
| apatite? | 3 | Small hex crystals with sector zoning; abnt in hem/lim vein |

Structures/Textures: quartz strained, grn boundaries slightly sutured. Fe-oxide fills fracture

Alteration: limonite replacing hematite

Interpretation: Fe-oxide is secondary vein filling of fractured quartz

Spec. No: 2951000025

Chip Desc: quartz vein with included phyllite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 85 | strained |
| muscovite | 7 | v.fine; in phyllite |
| biotite ? | 2 | V. fine, faintly pleochroic, intergrown w/ musc. in phyllite, somewhat fibrous |
| tourmaline | .5 | fairly abnt , in phyllite |
| limonite | 3 | secondary; in cracks, sutures; stains phyllite |
| hematite | 2 | in cracks; v. finely disseminated in phyllite |

Structures/Textures: Quartz strained, fractured; grain boundaries sutured; some polygonization at grain boundaries. Phyllite is included in vein quartz. Thin shear bands in phyllite, cutting across foliation. Some crumpling of foliation. A couple of thin phyllite seams occur along fractures in quartz.

Alteration: hematite and limonite is secondary

Interpretation: Quartz vein has been deformed, with fracturing and some recrystallization. Low metamorphic grade. Micas not well formed. "Biotite" appears to be forming as a result of introduction of Fe from Fe-oxides into mica structure. Quartz filling original fracture or breccia in phyllitic country rock?

Spec. No: 2951000026

Chip Desc: black, med. grained, hornblende pyroxenite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| diopside? | 57 | cpx; high relief, v. pale green; equigranular |
| hornblende | 40 | olive brown, "dirty"- appearing, larger poikilitic grains, and smaller, pale green, tabular to equant grains |
| plagioclase | 2 | vein filling |
| biotite | .5 | minor, replaces "dirty" hornblende |
| calcite | .5 | |
| apatite | tr. | |

Structures/Textures: Texture generally equigranular, w/ poikilitic hb. Probably metamorphic texture. Appears to be two generations of hb.

Alteration: hornblende appears "dirty". Minor biot replaces hb

Interpretation: Hornblende pyroxenite. Probably igneous protolith, with pyroxenes having been cumulus with subsequent crystallization of the hb, forming the large poikilitic grains. Later recrystallization, formed second generation hbs, and developed equigranular texture

Spec. No: 2951000027

Chip Desc: brecciated quartz (vein?); hematite-carbonate-filled fractures

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 74 | strained, fractured, grain boundaries somewhat sutured |
| hematite | 20 | fracture-filling |
| siderite? | 5 | some Fe-staining; fracture-filling |
| minnesotaite? | 1 | fibrous, looks like muscovite |

Structures/Textures: quartz brecciated; some suturing of grain boundaries

Alteration: hematite and carbonate are secondary-fracture filling

Interpretation: quartz vein? brecciated with subsequent fracture filling of carbonate and calcite. Hematite looks to post-date carbonate

Spec. No: 2951000028

Chip Desc: dark, porphyritic metavolcanic

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| hornblende | 50 | blue green, strong pleo; fibrous, matted |
| plagioclase | 40 | mostly fine-grained, sericitized; relict phenos approx 5% |
| epidote | 2 | yellow; in equil. with hb |
| chlorite | <1 | in equil. with hb |
| sericite | 1 | alters plag phenos |
| sphene | 5 | abnt, fine-grained, granular |
| pyrite | 1 | disseminated euhedral to subhedral grains |

Structures/Textures: relict phenocrysts

Alteration: sericite; fine sphene

Interpretation: metavolcanic, probably andesite; lower amphibolite facies (epidote amphibolite)

Additional Comments: chip looks amygdaloidal, but thin section shows a relict porphyritic texture

Spec. No: 2951000029

Chip Desc: greenish-grey, fine to med grained; looks sheared

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| hornblende | 50 | pale green, slightly pleo; idioblastic to fibrous |
| plagioclase | 20 | v. fine grained; matrix |
| epidote | 5 | mostly idioblastic |
| chlorite | 20 | occurs principally along crude fol; in equil w/ hb, ep |
| muscovite | 3 | |
| sphene | 2 | fine-grained, granular; secondary |

Structures/Textures: weak to mod. foliation; chlorite grains define fol, and are aligned parallel to fol., but wrap around hb idiomorphs. Fol produced by shear. Prob. relict porphyritic texture

Alteration:

Interpretation: metavolcanic; prob. andesite; hb idiomorphs prob. pseudomorphs after pyroxene. Sheared. Hb and chlorite are syntectonic. Prob. epidote-amphibolite facies (or upper greenschist)

Spec. No: 2951000030

Chip Desc: Light grey, porphyritic felsic metavolcanic

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 50 | relict polycrystalline phenos and fine matrix; grain boundaries generally irregular |
| plagioclase | 25 | relict phenos (& matrix?); sericitized |
| zoisite? | 20 | abnt; cornflower blue interference colors; parallel extinction |
| muscovite | 1 | |
| opaque | 2 | large grain; and forms along grain boundaries and cracks |
| limonite | 2 | secondary |

Structures/Textures: relict porphyritic texture; qz phenos recrystallized

Alteration: sericitization of plag; scattered secondary limonite

Interpretation: felsic metavolcanic; dacite?; with secondary development of zoisite and musc. Upper greenschist/lower amphibolite facies?

Spec. No: 2951000032

Chip Desc: med.-grained black/white metagabbro or diorite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| hornblende | 40 | pale green; mod. pleo; somewhat fibrous |
| plagioclase | 33 | heavily sausseritized; (orig. 50-55%) |
| epidote | 30 | secondary; replaces plag |
| biotite | 3 | |
| opaques | 3 | late, interstitial; altered to leucoxene |
| apatite | <1 | |

Structures/Textures: cut by vein of columnar to radiating epidote and minor calcite; xts perp. to vein

Alteration: mod to heavy sausserite; leucoxene

Interpretation: metagabbro; epidote-amphibolite grade

Additional Comments: Light brown color and columnar habit of vein mineral suggests zoisite, but optics work out to be epidote.

Spec. No: 2951000034

Chip Desc: fine-grained amphibolite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| hornblende | 55 | strong blue green pleo |
| plagioclase | 30 | v. fine, polygonal |
| diopside | 4 | assoc. w/ vein; prob. secondary |
| anhydrite? | 2 | vein mineral |
| apophyllite? | 1 | vein mineral |
| quartz | 4 | minor; in veins; matrix? |
| epidote? | 2 | vein mineral |
| sphene? | 2 | high relief mineral, assoc w. epidote, |
| pyrite | tr | assoc. w/ veins |

Structures/Textures: Thin veins cutting postdating metamorphic fabric

Alteration: Sausserite along margins of veins with diopside. Diopside prob. secondary, as only developed adjacent to epidote rich vein. Major vein shows a zonation: epidote + sphene(?) grading outward to diopside-sausserite. Two veins are qz-plg-anhdrite(?). Late vein of anhydrite(?) + apophyllite(?)

Interpretation: Protolith: mafic volcanic; amphibolite grade; later fracturing w/ calcium-rich alteration along veins. Anhydrite-apophyllite? cuts across qz veins

Additional Comments: Vein mineralization difficult to identify positively. Primary vein mineral looks to be epidote optically, but is chalky to colorless in chip. At least two and possibly three other vein minerals exist--anhydrite?, apophyllite?. These are identified as a "best guess".

Spec. No: 2951000036

Chip Desc: fine to med-grained, equigranular (meta?)diorite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| hornblende | 50 | green, pleo, somewhat patchy color; generally lighter in color around edges; mostly euhedral |
| biotite | 10 | olive green; some replaces hb, commonly in hb interiors; rest as individual grains |
| plagioclase | 30 | mod to heavily sericitized; some large poikilitic grains |
| quartz | 5 | interstitial |
| epidote | 3 | secondary |
| sphene | 2 | mostly secondary; couple of possibly primary grains w/ secondary overgrowths |
| apatite | .5 | |
| muscovite | | sericitic replacement of plag |

Structures/Textures: large, poikilitic plag; igneous texture, but looks recrystallized

Alteration: sericite, epidote, sphene

Interpretation: Diorite to quartz diorite, but looks recrystallized. Poikilitic plag suggests possibly a cumulate texture, with cumulus hornblende (or pyroxene?) and intercumulus plag. Biotite looks magmatic, although there has been later re-equilibration, w/ biot partially replacing hb (and hb replacing ppxn?) If metamorphic, prob amphibolite grade.

Additional Comments: This rock has a strange texture. Chip looks like it might be veined (w/ plag), but "vein" merges with remainder of rock. This could be some kind of secondary texture w/ plag introduced, however, I think it is most likely a metamorphosed cumulate texture.

Spec. No: 2951000038

Chip Desc: med-grained foliated metadiorite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| plagioclase | 70 | subhedral, tabular; lightly sericitized |
| microcline | 10 | blocky, anhedral, poikilitic w/ myrmekitic plag incl |
| quartz | 1 | |
| biotite | 13 | dark brown, subhedral to anhedral; pleochroic haloes around zircons |
| hornblende | 15 | green, pleo; many grains have lighter colored cores (replace orig. augite?) |
| augite | .5 | relict cores in hb |
| sphene | .5 | |
| epidote | tr | |
| chlorite | tr | |
| pyrite | tr | assoc. w/ biotite and hb |
| zircon | | numerous, mostly as small inclusions in biot. |
| allanite | tr | |

Structures/Textures: Foliation defined by biot and hb. Many plag grains somewhat polygonal. Biotite and hb appear to be magmatic.

Alteration: light sericitization of plag

Interpretation: hornblende monzodiorite; probably recrystallized. Foliation caused by crystallization under stress?, rather than being metamorphic?

Spec. No: 2951000040

Chip Desc: pink, med-grained granitoid

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| plagioclase | 55 | subhedral, tabular; mod to locally heavy sericite |
| microcline | 12 | interstitial, larger poikilitic grains |
| hornblende | 20 | green, pleo |
| augite | tr | few scraps of relict cores in hb |
| biotite | 1 | |
| opaque | 5 | interstitial |
| sphene | 1 | |
| apatite | 2 | |
| chlorite | 4 | replaces biotite; generally occurs in most seritized part |
| epidote | | minor |

Structures/Textures: hypidiomorphic granular

Alteration: sericitization of plag; chlorite after biotite

Interpretation: hornblende monzodiorite; igneous texture

Spec. No: 2951000042

Chip Desc: light purple v. fine grained phyllonite; sericitic

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 30 | v. fine grained; some ribbon qz (+fspr?) |
| muscovite | 60 | v. fine folia |
| sphene | 5 | (leucoxene?) anhedral, granular; probably alt of ilmenite |
| hematite | 5 | v. tiny dissem grains; strung out along foliation |

Structures/Textures: phyllonitic; weak development of S-C foliation; gentle asymmetric folding of folia;

Alteration: sphene (possibly leucoxene); fine hem

Interpretation: sheared felsic metavolcanic or possibly volcaniclastic

Additional Comments: too fine grained to determine protolith precisely; can't distinguish fsprs from quartz-- looks mostly like quartz

Spec. No: 2951000044

Chip Desc: lt. grey; v. fine-grained phyllite, mostly replaced by hematite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz/fspr | 25 | v. fine, occur in QF domains and as small porphyroclasts |
| muscovite | 25 | v. fine; defines folia |
| hematite | 50 | |

Structures/Textures: phyllonitic w/ small fspr porphyroclasts and "augen" of finely recrystallized quartz + fspr; folia defined by v. fine muscovite; porphyroclasts rotated

Alteration: over half of the rock in thin section is replaced by hematite

Interpretation: sheared felsic volcanic or volcaniclastic; later replacement by hematite

Additional Comments: Fine musc. (sericite) makes up 50% of unaltered rock; remainder is qz/fspr = 5% fine disseminated hem.

Spec. No: 2951000046

Chip Desc: quartz vein + phyllite; white powdery material occurring along vein boundary and quartz grain boundaries

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 60 | vein |
| quartz/fspr | 7 | v. fine, matrix in phyllite |
| sericite | 17 | v. fine |
| hematite | 6 | v. fine, disseminated (with leucoxene) |
| kaolinite | 10 | along margin between qz vein and phyllite; also as patches in phyllite |

Structures/Textures: quartz vein cutting through phyllite; quartz grains in vein are sutured; "wispiness" of disseminated hem in phyllite appears to outline relict shards

Alteration: kaolinite along vein boundary; also as patches in phyllite; fine disseminated hematite is secondary

Interpretation: possibly a metatuff; cut by qz vein, and altered

Additional Comments: percentages given are for phyllite

Spec. No: 2951000048

Chip Desc: lt. grey, phyllitic, felsic metavolcanic; porphyritic

Minerals: % Desc.

| | | |
|-------------|----|---|
| quartz/fspr | 42 | v. fine; some fspr remnants in porphyroclasts |
| muscovite | 50 | (sericite) defines foliation |
| hematite | 5 | v. finely disseminated |
| sphene? | 3 | abundant v. fine "grunge" |

Structures/Textures: phyllitic; foliation wraps around recrystallized porphyroclasts; porphyroclasts show some rotation; slight development of S-C cleavage.

Alteration: v. finely disseminated hematite and sphene? "grunge"

Interpretation: sheared felsic metavolcanic or tuff; greenschist facies

Spec. No: 2951000050

Chip Desc: hematite replacing? pinkish white chert

Minerals: % Desc.

| | | |
|----------|----|--|
| quartz | 40 | polygonal; mostly v. fine grained; some lenses and veins coarser |
| hematite | 60 | appears to be mostly secondary; fills veins, grain boundaries, though does define a crude layering |

Structures/Textures: crude layering defined by hematite; one vein of fine "quartzite" cuts obliquely across the crude layering. Late spaced fracture pattern cuts across early layering and "quartzite" vein. These fractures filled with hematite

Alteration: most if not all hematite secondary; certainly there has been remobilization of hem.

Interpretation: protolith probably "cherty" iron formation; later with later recrystallization and remobilization of both silica and hematite

Spec. No: 2951000051

Chip Desc: vein quartz plus Fe-oxides

Minerals: % Desc.

| | | |
|----------|----|--|
| quartz | 70 | vein |
| hematite | 25 | mostly crystalline, some later cryptocrystalline |
| limonite | 5 | replaces hematite |

Structures/Textures: quartz strained, partially polygonized esp. along grn boundaries. Hematite brecciated, healed w/ quartz

Alteration: cryptocrystalline hematite and limonite after crystalline hematite

Interpretation: breccia of hematite, filled w/ quartz. Later alt of hematite to cryptocrystalline hematite and limonite.

Spec. No: 2951000055

Chip Desc: quartz breccia, fractures filled w/ goethite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 70 | strained' polygonized along grain boundaries |
| hematite | 29 | mostly crystalline; some late cryptocrystalline |
| calcite | 1 | late fracture filling; fibrous, radial, w/ concentric banding |

Structures/Textures: brecciated quartz (vein?), fractures filled w/ hematite. Some late re-fracturing, fractures filled w/ fibrous calcite

Alteration:

Interpretation: quartz vein brecciated, fractures filled w/ hematite.. Later re-fracturing, filled w/ calcite

Spec. No: 2951000056

Chip Desc: hematite-filled quartz breccia

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| hematite | 70 | breccia filling, and replacing? quartz |
| limonite | 10 | replacing hematite |
| quartz | 18 | |
| calcite | 2 | late vein |

Structures/Textures: quartz breccia

Alteration: some late limonite

Interpretation: hematite filling fractures; may also replace quartz

Spec. No: 2951000057

Chip Desc: fractured or brecciated quartz

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 80 | highly strained; sheared into thin ribbons |
| hematite | 20 | fracture filling |
| limonite | | cryptocrystalline; occurs along interface between qz and hem |

Structures/Textures: Quartz highly strained; sheared into thin ribbons. Closely spaced discontinuities occur at high angle to ribbons, and are marked by v. thin line of finely polygonized qz. Hematite postdates the shearing, and fills along some shear discontinuities

Alteration: Limonite alters earlier hematite

Interpretation: Quartz sheared and fractured. Later introduction of hematite along fractures and some shear discontinuity.

Spec. No: 2951000061

Chip Desc: quartz

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--------------|
| quartz | 100 | strained |

Structures/Textures: some suturing of grain boundaries, but v. little recryst. Closely spaced, parallel, discontinuous microcracks.

Alteration:

Interpretation:

Spec. No: 2951000063

Chip Desc: goethite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| goethite | 99 | |
| quartz | 1 | v. fine, polygonal, fills fine fractures |

Structures/Textures: numerous fracture sets, mostly filled w/ remobilized lim; quartz fills earlier set, then offset by later fracture set filled w/ remobilized lim.

Alteration:

Interpretation:

Spec. No: 2951000064

Chip Desc: thin layered limonitic siltstone

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|------------------------|
| quartz | 40 | fine, polygonal grains |
| limonite | 60 | matrix |

Structures/Textures: qz grains are clastic; but have been recrystallized

Alteration: limonite?

Interpretation: meta-siltstone; Fe-oxide matrix

Spec. No: 2951000067

Chip Desc: graphitic phyllite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| graphite | 50 | thin, "wispy", opaque |
| sericite | 10 | v. fine |
| qz/fspr | 30 | v. fine, partially replaced by sericite |
| hematite | 10 | (+ some lim); isolated anhedral grains |

Structures/Textures: graphite defines fol; wraps around tiny "augen" shaped domains of quartz/feldspar

Alteration: sericite; hematite after magnetite?

Interpretation: Protolith probably a carbonaceous metasediment

Additional Comments: "augen" pseudomorphed by sericite (+ chl?--looks like ser., but has low bir, but does not appear to be pleo--1% MgO might indicate presence of chl). Note high values of TiO₂, P₂O₅, and F. Can't see this in mineralogy--too fine grained.

Spec. No: 2951000069

Chip Desc: hematite replacing meta-siltstone or tuff. A couple of larger flattened clasts or lapilli visible

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 25 | v. fine, somewhat flattened grains; a few polycrystalline "porphyroclasts" and veins |
| sericite | 30 | abnt; defines fol; appears to replace all orig. minerals but qz. |
| hematite | 45 | secondary; replaces sericite |

Structures/Textures: Foliated; fol. wraps around porphyroclasts. Subparallel microfaults, oblique to fol, offset qz veins, and warp sericite. "Veins" consist of a few slightly coarser -grained qz segregations parallel to fol.

Alteration: hematite is secondary and appears to replace sericite

Interpretation: Protolith: siltstone prob. volcaniclastic or tuff. Deformed and metamorphosed to greenschist facies, producing fol. Later introduction and replacement by hematite. Microfractures postdate hematite.

Spec. No: 2951000072

Chip Desc: hematite-rich "cherty" iron fm

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 35 | microcrystalline--chert |
| hematite | 65 | martite; also replaces chert; approx half is cryptocrystalline |

Structures/Textures: thin layering; weak fol oblique to layering--visible only in hematitic portions

Alteration: Replaces primary magnetite; also replaces chert; primary layering still visible.

Interpretation: "cherty" iron formation, with replacement of magnetite and chert by secondary hematite

Spec. No: 2951000074

Chip Desc: thin layered chert + minor hematite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 90 | microcrystalline--chert |
| hematite | 10 | pseudomorphs earlier magnetite?; and as v. fine disseminated "crud" |

Structures/Textures: thin layering

Alteration: hematite secondary, replaces magnetite?

Interpretation: "cherty" iron formation, oxidized

Spec. No: 2951000076

Chip Desc: pink/black, med-grained magnetite-carbonate-quartz rock

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| hematite | 50 | anhedral, fracture; |
| carbonate | 30 | siderite/ankerite?--(or rhodochrosite?), anhedral to euhedral; "dirty" appearance |
| quartz | 20 | mostly vein; also intergrown w/ hematite-carbonate |
| minnesotaite? | | fibrous, secondary mineral; looks a little like serpentine, but birefringence too high |

Structures/Textures: some vein quartz

Alteration: minnesotaite? may be secondary; hematite after magnetite--or is hematite primary?

Interpretation: hydrothermal?

Additional Comments: Carbonate may be manganiferous. Note relatively high MnO₂ in analysis.

Spec. No: 2951000078

Chip Desc: hematite-pink carbonate-quartz; approx one-half of chip is massive hematite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| hematite | 50 | some martite; intergrown with carbonate |
| carbonate | 37 | rhodochrosite? somewhat dirty in appearance; appears to replace quartz |
| quartz | 10 | appears to be vein quartz |
| minnesotaite? | 3 | slightly greenish, fine grained, somewhat fibrous layer silicate; low bir; intergrown w/carbonate (bir may be too low; but is v. fine grained) |

Structures/Textures:

Alteration: hematite/carbonate appear to replace quartz; is alt hydrothermal?

Interpretation: possibly manganiferous iron formation?

Additional Comments: Carbonate is probably manganiferous; note relatively high MnO₂.

Spec. No: 2951000083

Chip Desc: lt. brown phyllite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|----------------------------|
| quartz | 20 | v. fine grained |
| sericite | 70 | define foliation |
| hematite | 5 | v. fine, "dusty", anhedral |
| sphene? | | fine, anhedral "grunge" |

Structures/Textures: Primary fragmental texture well camouflaged by metamorphism and deformation. Foliated, with foliation crenulated, in some places disharmonically

Alteration: much of fine opaques prob. secondary; much fine, probably Ti-rich, "grunge"

Interpretation: Probably a tuff, though fairly low SiO₂ in analysis. Probably two deformations: first forming foliation (though could have formed from a flow banding), second causing crenulation of foliation

Spec. No: 2951000084

Chip Desc: lt. brown, weakly foliated phyllite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 3 | mostly v. fine |
| feldspar | 5 | v. fine; in a few small polycrystalline porphyroclasts |
| sericite | 77 | defines weak fol |
| hematite | 14 | fine, anhedral |
| py? | 1 | |

Structures/Textures: weak fol; clast outlines barely visible, mostly lenticular

Alteration:

Interpretation: probably a metatuff or tuffaceous siltstone--not much qz; clasts are probably fine felsic volc fragments, replaced by sericite. Greenschist grade

Additional Comments: looks like more fspr than qz, based on alt; striations not visible

Spec. No: 2951000085

Chip Desc: laminated siltstone

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 2 | |
| feldspar | 3 | |
| sericite | 85 | |
| opaques | 10 | fine, dissem; thin seams define weak clvg |

Structures/Textures: Laminated; subtly graded; weak cleavage oblique to lamination, defined by trains of fine opaques, and a few spaced fractures filled w/ v. fine qz+fspr (looks chertified). Minor crumpling fol along one edge of slide (clvg axial planar to this), but is not carried through whole slide

Alteration:

Interpretation: metasiltstone, prob w/ high felsic volc content. Greenschist grade

Spec. No: 2951000087

Chip Desc: laminated hematitic siltstone

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|-------------------------|
| quartz | 5 | v. fine; relict clasts |
| sericite | 70 | |
| hematite | 20 | |
| sphene | 5 | fine, granular clusters |

Structures/Textures: laminated; foliation perpendicular to layering, defined by sericite and elongate hematite

Alteration:

Interpretation: Laminated siltstone. Laminae vary in hematite content, generally between richer and poorer hematite contents, suggesting Fe-oxide is primary. Rock has been metamorphosed to greenschist facies, with probable deformation producing weak foliation.

Spec. No: 2951000089

Chip Desc: thinly interlayered siltstone and ss; sericitic

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|----------------------|
| quartz | 35 | rounded clasts |
| microcline | .5 | rounded clasts |
| plagioclase | tr | clasts |
| sericite | 60 | |
| hematite | 5 | v. fine disseminated |

Structures/Textures: Thinly layered; alternating between siltstone and ss.; clasts well rounded; perhaps slightly graded--equivocal. Layers bent; probably folded on larger scale. Well defined foliation, defined by sericite, cuts across layering at high angle.

Alteration: hematite probably secondary

Interpretation: Interlayered ss/siltstone. Turbiditic? Deformed and weakly metamorphosed (greenschist facies).

Additional Comments: Note lack of volcanic fragments, and relatively minor feldspar content of coarser clasts.

Spec. No: 2951000091

Chip Desc: light purple, fine-grained quartzite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|-----------------------------------|
| quartz | 92 | strained, somewhat recrystallized |
| feldspar | 5 | pits in thin section |
| opaques | 3 | fine; along grain boundaries |

Structures/Textures: quartz grains strained; boundaries somewhat sutured. Essentially bimodal grain size: larger, generally lenticular grains, w/ small polygonal grains along larger grain boundaries. I think the smaller grains are result of deformation/recrystallization rather than primary bimodal distribution

Alteration:

Interpretation: quartzite; strained, with recrystallization along grain boundaries

Spec. No: 2951000093

Chip Desc: red, hematitic siltstone

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 18 | (+ fspr?) fine grained; subangular clasts; some chert |
| hematite | 50 | matrix |
| chlorite? | 30 | v. fine; intergrown w/ hematite; weak pleo; low bir |
| sphene | 2 | fine granular; secondary; some leucoxene |

Structures/Textures: v. fine grained; clastic

Alteration: sphene/leucoxene secondary

Interpretation: hematitic siltstone; weakly metamorphosed

Spec. No: 2951000095

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| chlorite | 72 | defines fol |
| quartz | 15 | mostly v. fine, generally lenticular grains; a few composite grains |
| leucoxene | 5 | fine, dissem; mostly entrained along fol |
| kaolinite | 8 | fills in larger "augen"-shaped spaces; replacing feldspar? |

Structures/Textures: fol deflected around larger grains; second, spaced, discontinuous clvg at high angle to primary fol, and deflects primary fol

Alteration: some hematite staining

Interpretation: prob. metasedimentary

Spec. No: 2951000097

Chip Desc: reddish, fine-grained quartzite; porous

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 70 | |
| feldspar | 23 | generally altered |
| sericite | 2 | v. fine grained; mostly in matrix |
| magnetite | 1 | small, euhedral grains |
| hematite | 4 | mostly fine, disseminated, ragged to "dusty" grains |
| tourmaline | tr | |
| zircon | tr | |

Structures/Textures: some recryst. of quartz

Alteration: slight sericitization of fsp

Interpretation: feldspathic quartzite; weakly metamorphosed

Spec. No: 2951000099

Chip Desc: red, hematitic siltstone w/ thin ss interlayers

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 25 | clasts, generally rounded |
| sericite | 55 | defines fol |
| hematite | 20 | fine, disseminated; may replace orig magnetite |
| zircon | tr | |

Structures/Textures: Primary layering, folded into tight microfolds. Layering consists of alternating siltstone and fine ss layers. Qz grains generally rounded. Axial plane foliation cuts across primary layers

Alteration: hematite?

Interpretation: Interlayered ss/slt; folded, metamorphosed. Greenschist facies

Spec. No: 2951000101

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| microcline | 10 | individual crystals, and in composite lithic fragments |
| sericite | 79 | v. fine; matrix |
| biotite | 1 | greenish; occurs in a couple of fragments |
| hematite | 10 | v. fine disseminated; secondary |

Structures/Textures: Pyroclastic, w/ relict flow banding. Many of clasts rounded.

Alteration: abundant fine disseminated hematite

Interpretation: lithic tuff, probably of trachytic composition

Spec. No: 2951000103

Chip Desc: lt. greenish grey chlorite schist

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 30 | v. fine-grained; polygonal |
| chlorite | 50 | defines primary fol; pale greyish green; faintly pleo |
| muscovite | 20 | generally idioblastic, cutting across primary fol. |
| cordierite? | 1 | small, roundish, colorless, low relief |
| ilmenite | 3 | (orig 5%) skeletal remnants of a prophyroblastic mineral; some leucox & sphene assoc. |

Structures/Textures: Primary foliation defined by chlorite; asymmetrically crenulated, w/ development of weak spaced cleav--prob. pressure solution. Muscovite generally aligned w/ second fol. Primary fol. wraps around ilmenite? porphyroblasts. These porphyroblasts are stretched, and perhaps broken, and altered.

Alteration: Ilmenite altering to leucoxene + sphene

Interpretation: Protolith: Mg-Al rich metasediment. Two deformations, possibly two metamorphisms. Amphibolite grade?

Spec. No: 2951000105

Chip Desc: brown, fine grained, laminated to thin bedded

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|------------------------------------|
| biotite | 55 | v. fine |
| antigorite? | 25 | fine, colorless, non pleo, low bir |
| calcite | 20 | fine, disseminated throughout |

Structures/Textures: laminated to thin bedded; weak fol at high angle to layering defined by some fibrous chlorite (note: not all chlorite aligns with this fol--only the most elongate grains do)

Alteration:

Interpretation: metasediment; lower amphibolite facies

Additional Comments: Strange assemblage; not sure what kind of sedimentary protolith this represents. Antigorite doesn't seem to fit with biotite. Bir too low for sericite. Could be chlorite, but lack of color and pleochroism, bir, and fibrous habit fit antigorite better. Note fairly high Mn in chem analysis.

Spec. No: 2951000107

Chip Desc: lt. grey laminated metasediment

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 10 | relict clasts |
| sericite | 83 | |
| hematite | 7 | disseminated; prob replace primary magnetite |

Structures/Textures: Laminated, mostly v. fine grained, w/ thin beds of slightly coarser grained clastic quartz. Relict quartz clasts are flattened in plane of foliation; some of the larger grains have pressure shadows. Foliation cuts across layering. Porphyroclasts? of what looks to be fine granular quartzofeldspathic material have pitted out, and leave holes in section.

Alteration: hematite probably secondary

Interpretation: Siltstone w/ thin fine ss. laminae. Deformation and metamorphism produced foliation; greenschist facies.

Spec. No: 2951000109

Chip Desc: hematitic sandstone

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 45 | clasts; mostly single crystal grains; a few polycrystalline |
| rock fragments | 20 | Mostly felsic plutonic and metamorphic clasts. Lesser maficplutonic, intermediate volcanic, clastic sedimentary, jasper and iron formation. |
| plagioclase | 1 | |
| microcline | 2 | |
| biotite | tr | |
| hornblende | tr | |
| epidote | 1 | |
| hematite | 30 | matrix |
| magnetite | tr | |
| ilmenite | tr | |
| pyrite | tr | |

Structures/Textures: Clasts sand sized; generally angular; matrix supported.

Alteration:

Interpretation: Immature ferruginous sandstone. Not metamorphosed. I don't think this is a Precambrian sediment

Spec. No: 2951000119

Chip Desc: grain mount; marble? one lg. grain laminated

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| calcite | 80 | v. fine |
| biotite | 10 | occurring in most grains |
| quartz | <5 | occurs in one grain |
| magnetite | 3 | euhedral-subhedral |
| hematite | 2 | alt. of hematite |
| unid. layer | <5 | fibrous; low bir.; v. fine; occurs in one clast silicate |

Structures/Textures: one grain laminated

Alteration: minor alt of magnetite to hematite

Interpretation: micaceous marble? Is carbonate primary?

Spec. No: 2951000127

Chip Desc: grain mount; grains of hematite and quartzite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|----------------------------------|
| quartz | 49 | mostly fine grained granoblastic |
| hematite | 50 | |
| calcite | 1 | |

Structures/Textures: Quartz grains are composite and are fine-grained granoblastic. Most of quartz "clasts" are separate from hematite "clasts". Intergrowth in individual grains is minimal

Alteration: minor limonite

Interpretation: probably iron formation; metamorphosed so that original siliceous material is now fine grained quartzite

Spec. No: 2951000129

Chip Desc: grain mount; mostly grains of hematite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|-------------------|
| hematite | 95 | |
| quartz | 5 | very fine grained |

Structures/Textures: quartz very fine grained, granoblastic; generally intergrown with hematite

Alteration: minor limonite

Interpretation: iron formation? quartz has been recrystallized

Spec. No: 2951000131

Chip Desc: grain mount: grains of hematite and fine-grained quartzite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 50 | fine-grained, granoblastic |
| hematite | 50 | |
| unid. opaque | tr | highly reflective (steel from drill bit?) |

Structures/Textures:

Alteration:

Interpretation: probably iron formation; granoblastic nature of quartz indicates metamorphism

Spec. No: 2951000133

Chip Desc: grain mount: fine-grained quartzite and hematite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 52 | fine-grained, granoblastic |
| hematite | 25 | |
| limonite | 20 | |
| calcite | 3 | concentric banding w/ radiating fibers; colloform?, algal? |

Structures/Textures:

Alteration: limonite

Interpretation: probably iron formation; granoblastic quartz indicates metamorphism

Spec. No: 2951000135

Chip Desc: grain mount: mostly hematite and limonite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|-----------------------------------|
| hematite | 45 | two types: darker and redder |
| limonite | 45 | |
| quartz | 5 | |
| calcite | 5 | probably vein fillings; colloform |

Structures/Textures: some grains have calcite filled grains and tiny quartz-filled fractures

Alteration: limonite and red hematite are secondary

Interpretation: probably iron formation; calcite grains are probably from veins

Spec. No: 2951000139

Chip Desc: grain mount: mostly Fe-oxides

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|------------------------------|
| hematite | 33 | finely crystalline |
| limonite | 60 | cryptocrystalline, secondary |
| calcite | 5 | |
| quartz | 2 | v. fine grained; "cherty" |

Structures/Textures:

Alteration: secondary limonite (+ hematite?)

Interpretation: probably from iron formation

Spec. No: 295000143

Chip Desc: grain mount: mostly Fe-oxides

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 3 | |
| calcite | 3 | colloform |
| hematite | 50 | mostly finely crystalline; some cryptocrystalline |
| limonite | 44 | secondary; cryptocrystalline |

Structures/Textures:

Alteration: secondary cryptocrystalline limonite and hematite

Interpretation: probably from iron formation

Spec. No: 2951000169

Chip Desc: dark, med. grained metagabbro?

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| hornblende | 30 | lt. green/weak-mod. pleo |
| epidote | 35 | occurs both as larger idioblasts and in fine, granular masses |
| plagioclase | 26 | mostly remnants, some laths remaining |
| biotite | 5 | |
| apatite | 1 | long prisms |
| sphene | 3 | fairly lg grains, interstitial; could be a replacement of ilmenite; also as small secondary grains enclosed within hornblende grains |

Structures/Textures:

Alteration: secondary epidote and sphene (metamorphic)

Interpretation: Protolith: diorite or gabbro--prob. gabbro based on low silica in chemical analysis; epidote-amph. facies?

Spec. No: 2951000170

Chip Desc: med. grained metagabbro

| Minerals: | % | Desc. |
|------------------|----------|---|
| hornblende | 35 | lt. green/weak-mod. pleo |
| plagioclase | 25 | mostly remnants of laths |
| epidote | 30 | larger idioblasts and fine granular masses replacing plag |
| biotite | 5 | |
| sphene | 3 | blocky, interstitial; replaces ilmenite? |
| apatite | 1 | long prisms |

Structures/Textures:

Alteration: secondary epidote and sphene (metamorphic)

Interpretation: Protolith: metagabbro

Spec. No: 2951000172

Chip Desc: hematite stained qzite/ with yellowish-red fibrous mineral

| Minerals: | % | Desc. |
|------------------|----------|--|
| quartz | 80 | fine-grained granoblastic |
| stilpnomelane? | | thin sheaf-like blades and fibers; deep red, semi-transparent, non-pleo replacing stilpnomelane? |
| hematite | 5 | small anhedral masses partially replaced by limonite |
| limonite | 10 | |
| leucoxene | 5 | assoc. w/ limonite |

Structures/Textures:

Alteration: hematite is secondary; partially replaces fibrous mineral (stilpnomelane?)

Interpretation: iron formation, recrystallized; with stilpnomelane?, later partially replaced by hematite

Spec. No: 2951000173

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 50 | v. fine grained, fibrous |
| hematite | 20 | crystalline, cryptocrystalline, and fibrous |
| limonite | 27 | replaces hematite |
| pyrite | 3 | |

Structures/Textures: fibers deformed along numerous fine grained fractures; at least two fracture sets, quartz in both is principally fibrous, with fibers normal to vein walls

Alteration: cryptocrystalline hematite and limonite replaces earlier hematite; slight oxidation of pyrite along edges of grains

Interpretation: Iron formation; fractured and possibly slightly sheared deforming quartz fibers. At least two generations of hematite.

Spec. No: 2951000174

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| stilpnomelane? | 60 | thin, bladed, occurs in mats; pleo cream to red brown; lacks birdseye |
| quartz | 10 | intergrown with hem/lim fibers |
| calcite | 10 | |
| hematite | 10 | martite; 5% cryptocrystalline; some fibrous, possibly replacing stilpnomelane. |
| pyrite | 5 | irreg.; probably late; assoc with some calcite |
| magnetite | 5 | partially replaced by hem |

Structures/Textures:

Alteration: hematite replacing magnetite; secondary hematite replacing earlier hematite and stilpnomelane

Interpretation: probably iron formation

Spec. No: 295000175

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 50 | fine grained, polygonal |
| hematite | 30 | mostly crystalline (martite), some later cryptocrystalline; |
| magnetite | tr | remnants in martite |
| limonite | 19 | replaces hematite and fibrous mineral--stilpnomelane? |
| apatite | 1 | larger blocky grains |

Structures/Textures:

Alteration: secondary hematite and limonite after hematite and stilpnomelane(?)

Interpretation: oxidized iron formation;

Spec. No: 2951000176

Chip Desc: oxidized iron formation; some banding visible

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 20 | both somewhat granoblastic and fibrous; fibrous varieties are intergrown with hematite which has replaced stilpnomelane |
| stilpnomelane | 35 | fibrous to bladed, matted; lacks birdseye |
| hematite | 36 | blocky euhedral, crystalline (martite); cryptocrystalline replaces stilpnomelane |
| limonite | 2 | |
| calcite | 5 | |
| minnesotaite | 2 | fibrous; mod relief, high birefringence; intergrown w/ stilp. |
| pyrite | tr | |
| magnetite | tr | remnants in martite crystals |

Structures/Textures: primary layering

Alteration: later hematite (and minor limonite) replacing stilpnomelane

Interpretation: oxidized iron formation; hematite replaces (earlier hem?) and stilpnomelane

Spec. No: 2951000180

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 95 | fibrous, radiating--to finely granoblastic |
| hematite | 5 | small remnant at edge of slide; intergrown w/ quartz (some fibrous); occurs as blocky grains and fibrous replacements(?) of stilpnomelane(?) |

Structures/Textures:

Alteration: hematite secondary

Interpretation: slightly recrystallized chert; with a small portion of secondary hematite

Spec. No: 2951000181

Chip Desc: banded iron formation; greenish color; oxidized

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 10 | granoblastic and fibrous |
| minnesotaite | 40 | greenish-gray; fibrous, radiating, short fibers, low 2V(-) |
| stilpnomelane | 30 | thin blades, matted, pleo: golden yellow to olive brown pleo; generally intergrown with minnesotaite |
| hematite | 15 | occurs as blocky grains, and secondary cryptocrystalline; replaces earlier hem and some stilpnomelane |
| limonite | | minor |
| calcite | 2 | |

Structures/Textures: primary thin layering

Alteration: secondary hematite

Interpretation: Fe-silicate iron formation; oxidized; one thin vein containing quartz, hematite, and minor stilpnomelane (replaced) cuts across layering

Spec. No: 2951000182

Chip Desc: altered metagabbro or diabase

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| plagioclase | 50 | orig. approx. 70%; sausseritized; originally zoned, cores now mostly epidote |
| amphibole | 10 | actinolite or actinolitic hb; pale green, lightly pleo; somewhat fibrous; heavily Fe-stained partially replaced by chlorite |
| chlorite | 10 | replaced actinolite |
| epidote | 15 | euhedral to anhedral |
| sphene | 4 | blocky pseudomorphs of ilmenite(?); also fine granular grains assoc w. chlorite |
| biotite | 1 | incipient |
| kaolinite | 10 | mostly assoc. w/ breakdown of actinolite |

Structures/Textures: original diabasic texture

Alteration: plag sausseritized; actinolite altering to chlorite and kaolinite; sphene secondary

Interpretation: Protolith: gabbro or diabase; prob metamorphosed to greenschist facies; later altered with actinolite altering to chlorite and kaolinite; kaolinite might suggest a hydrothermal alt.

Spec. No: 2951000183

Chip Desc: fine- to med-grained metadiabase

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| plagioclase | 44 | laths euhedral to subhedral; a few larger relict pheno's |
| hornblende | 35 | blue green, lightly pleo; some poikilitic, possibly after ophitic pyroxene |
| epidote | 10 | euhedral |
| chlorite | 5 | interstitial; generally assoc. w. hb and epid, but doesn't replace hb |
| biotite | 1 | |
| sphene | 3 | larger blocky grains, perhaps after ilmenite?; smaller anhedral grains assoc w/hb |
| calcite | 2 | |

Structures/Textures: possibly porphyritic

Alteration:

Interpretation: Protolith: diabase or basalt; upper greenschist or epidote amphibolite facies

Spec. No: 2951000184

Chip Desc: altered fine-grained metagabbro

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| plagioclase | 48 | generally small laths |
| hornblende | 5 | actinolitic?; mostly relics; replaced by chlorite |
| chlorite | 25 | replaces hornblende |
| biotite | 3 | |
| epidote | 5 | |
| sphene | 4 | larger blocky grains after ilmenite?; small anhedral grains assoc. w/ chlorite |
| kaolinite | 10 | Fe-stained; typically occurs in patches assoc w/ chlorite, replaces plag and hb |

Structures/Textures:

Alteration: chlorite, kaolinite, epidote, sphene

Interpretation: Protolith: fine-grained metagabbro or diabase; metamorphosed to upper greenschist facies; later alteration to chlorite and kaolinite (+ sphene and epidote?). Alteration hydrothermal?

Spec. No: 2951000187

Chip Desc: brownish-white fine grained feldspathic quartzite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 86 | granoblastic, with irreg. grain boundaries |
| kaolinite | 10 | completely replaces fspr? grains |
| sericite | 2 | along grain boundaries |
| limonite | 2 | in fine fractures and stains kaolinite |
| tourmaline | tr | |

Structures/Textures: clastic, grain supported; a few fine fractures filled w/ limonite

Alteration: kaolinite--probably replaces feldspars

Interpretation: Protolith: feldspathic sandstone

Spec. No: 2951000201

Chip Desc: massive hematite and limonite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|-----------------------|
| hematite | 85 | massive |
| calcite | 7 | fills small fractures |
| quartz | 3 | small veins |
| limonite | 5 | later alt |

Structures/Textures: hematite cut by numerous fine fractures which are filled mostly with calcite and some quartz; calcite appears to be later than quartz

Alteration: limonite

Interpretation: iron formation?

Spec. No: 2951000202

Chip Desc: fine-grained quartzite veined w/ Fe-oxides

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 90 | fine-grained, granoblastic |
| hematite | 5 | in larger vein |
| limonite | 3 | in veins roughly perpendicular to larger vein, with calcite |
| calcite | | |

Structures/Textures: two vein sets: larger hematite-quartz vein, truncates smaller calcit-limonite veins. These veins may have merged into larger vein, but are truncated and slightly offset by thin quartz vein

Alteration: calcite and Fe-oxides are introduced

Interpretation: quartzite; fractured and veined with calcite-limonite and hematite-quartz

Spec. No: 2951000207

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--------------------------------------|
| quartz | 45 | mostly small grains, appears clastic |
| nontronite? | 40 | brownish green clay mineral; |
| minnesotaite? | 5 | very pale green mica, lacks birdseye |
| limonite | 10 | irregular spots and patches |

Structures/Textures: looks like some original layering

Alteration: heavy "coating" of greenish clay mineral--nontronite?; limonite

Interpretation: looks clastic--siltstone--possibly a greywacke; heavily altered, perhaps hydrothermal

Spec. No: 2951000229

Chip Desc: massive limonite/hematite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--------------|
| limonite | 95 | massive |
| quartz | 5 | in veins |

Structures/Textures: brecciated; quartz veins heal some fractures; larger quartz vein is brecciated and recemented w/ limonite

Alteration: limonite/hematite is secondary

Interpretation: brecciated limonite/goethite, possibly forming along fault or slump

Spec. No: 2951000239

Chip Desc: fractured quartz (vein?); healed with limonite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 90 | vein quartz, fractured; deformed into thin ribbons |
| limonite | 10 | |
| calcite | .tr | tiny grains form along ribbon boundaries |

Structures/Textures: Quartz fractured; individual grains sheared into thin ribbons, with tiny calcite grains forming along ribbon boundaries. Ribbons are bent (slightly folded)

Alteration:

Interpretation: Probably a quartz vein, fractured, and filled with limonite. Deformation (shearing?) produced thin ribbons in quartz

Spec. No: 2951000245

Chip Desc: massive goethite with small carbonate rhombs

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| goethite | 88 | massive; |
| calcite | 5 | porphyroblastic? rhombs |
| stilpnomelane | 5 | tiny needles assoc w/ healed fractures |
| hematite | 2 | fine martite grains |
| quartz | tr | |

Structures/Textures: Three sets of veins: 1. early, healed w. stilpnomelane, 2. cacite fillings; 3. late fractures w/ qz

Alteration: hematite replacing primary magnetite; later limonite

Interpretation: Some recrystallization of limonite indicated by healed stilpnomelane fractures and later growth of calcite rhombs

Spec. No: 2951000246

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| stilpnomelane | 65 | fine needles, matted |
| calcite | 10 | in veins and patches in stilp |
| quartz | 8 | in veins assoc w/ calcite, also layered w/ stilp |
| hematite | 10 | martite; replacing magnetite |
| magnetite | 5 | remnants in martite grains |
| limonite | 2 | in veins |

Structures/Textures: thin layered, mostly masked by stilpnomelane; fractures filled w/ qz-cc and some stilpnomelane

Alteration: hematite replacing primary magnetite; minor limonite; calcite appears to have been introduced

Interpretation: iron formation? somewhat metamorphosed; fractured and veined w/ qz-cc. Calcite probably introduced.

Spec. No: 2951000267

Chip Desc: limonitic metavolcanic?

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| chlorite | 5 | pale green |
| plagioclase | 10 | mostly as remnants in chlorite matrix |
| limonite | 30 | in cracks, grain boundaries near cracks, and stains |
| leucoxene | 3 | ragged |
| sphene | | v. fine-grained, assoc w/ leucoxene |
| nontronite? | 2 | v. fine, greenish layer silicate alt mineral; assoc w/ limonite |

Structures/Textures: appears to be a relict volcanic texture, masked in chlorite

Alteration: chlorite secondary; leucoxene (after ilmentite?) ; limonite and assoc. green alt mineral occurs mostly along fractures; postdates chlorite

Interpretation: Protolith: probably metavolcanic, probably andesite. Limonite along cracks, seems to stain rock--probably introduced.

Spec. No: 2951000268

Chip Desc: gray metavolcanic(?), pitted, contains small patches of hematitic alt; slightly porphyritic

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| plagioclase | 52 | partially recrystallized; a few larger phenocrysts; light sericite on pheno's |
| chlorite | 35 | forms matrix, pervasive |
| biotite | <1 | |
| leucoxene | 2 | from ilmenite |
| hematite | 3 | from magnetite; and v. fine "powder" |
| sphene | 1 | fine, assoc w/ opaques |
| ser | 1 | |
| unid. clay | 3 | pale greenish brown alt mineral assoc w/ pits |

Structures/Textures: slightly porphyritic

Alteration: chlorite; also a greenish clay mineral (nontronite?), probably what is pitting out; opaques originally magnetite and ilmenite, altered to hematite and leucoxene

Interpretation: metavolcanic, probably andesite; greenschist facies (or caused by alteration)

Spec. No: 2951000272

Chip Desc: greenish brown, fragmental, w/ rounded, siliceous clasts

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 20 | fine-grained granoblastic; mostly in larger clasts?; a few angular grains in matrix |
| biotite? | 33 | v. fine needles, greenish brown, but weakly pleo; incipient?; forms in matrix and conc along silica clast peripheries w/ needles projecting inward; some smaller clasts matted w/ biot |
| pyrite | 5 | irreg; forms especially along periphery of siliceous clasts |
| other opaques | 30 | v. fine disse--graphite?; replaces some smaller clasts |
| limonite | 10 | late, mostly from alt of pyrite |
| clay | 2 | green, fills fractures and a few patches |

Structures/Textures: conglomeratic, intraformational; texture looks pyroclastic, but clasts are not volcanic

Alteration: limonite and late greenish clay mineral in fractures

Interpretation: Intraformational conglomerate; possibly formed by slumping or other soft sediment deformation. Protolith: probably iron formation, graphitic? Siliceous clasts probably orig. chert. Probably greenschist facies metamorphism.

Additional Comments: Greenish brown layer silicate mineral probably incipient biotite (doesn't look like stilpnomelane--though that's possible)

Spec. No: 2951000273

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 20 | fine grained granoblastic; mostly in larger oblong clasts; a few grains in matrix |
| biotite? | 58 | v. fine grained; greenish-brown, but weak pleo; mostly in matrix |
| limonite | 8 | after pyrite |
| pyrite | 4 | late; mostly around periphery of siliceous clasts |
| graphite? | 10 | v. fine dissem.; abnt in clasts, some in matrix |

Structures/Textures: fragmental; flow texture; amygdaloidal

Alteration: limonite after pyrite

Interpretation: Intraformational conglomerate; possibly formed by slumping or other soft sediment deformation. Protolith: probably iron formation, graphitic? Probably greenschist facies metamorphism.

Additional Comments: Greenish brown layer silicate mineral probably incipient biotite (doesn't look like stilpnomelane--though that's possible)

Spec. No: 2951000274

Chip Desc: greenish gray, fragmental w/ siliceous clasts; contains sulfide

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 45 | 20% fine ,granoblastic; oblong clasts(?); 20% matix |
| biotite | 38 | v. fine, greenish-brown; matix |
| limonite | 7 | after pyrite |
| hematite | 1 | finely crystalline; after pyrite |
| pyrite | 10 | late; irreg., mostly around periphery of siliceous clasts |
| graphite? | 4 | v. fine dissem.; abnt in a few small clasts and some matrix |

Structure/Texture: conglomeratic, intraformational; texture looks pyroclastic, but clasts are not volcanic

Alteration: limonite after pyrite

Interpretation: Intraformational conglomerate; possibly formed by slumping or other soft sediment deformation. Protolith: probably iron formation, graphitic? Probably greenschist facies metamorphism.

Additional Comments: Greenish brown layer silicate mineral probably incipient biotite (doesn't look like stilpnomelane--though that's possible)

Spec. No: 2951000275

Chip Desc: conglomerate with ovoid siliceous clasts

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 50 | fine-grained, granoblastic; mostly as vesicle? fillings |
| biotite | 30 | v. fine-grained needles |
| pyrite | 10 | late; irreg. |
| limonite | 7 | after py |
| hematite | 1 | finely crystalline; after pyrite |

Structures/Textures: conglomeratic; intraformational

Alteration: limonite (and minor hematite) after pyrite

Interpretation: Intraformational conglomerate; possibly formed by slumping or other soft sediment deformation. Protolith: probably iron formation. Siliceous clasts probably orig. chert. Probably greenschist facies metamorphism.

Additional Comments: Greenish brown layer silicate mineral probably incipient biotite (doesn't look like stilpnomelane--though that's possible)

Spec. No: 2951000276

Chip Desc: fragmental with siliceous clasts; Fe-stained

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 84 | fine, granoblastic, forms in larger ovoidal clasts, and in matrix |
| biotite | 5 | v. fine needles, greenish brown, but weakly pleo; incipient? |
| pyrite | 1 | |
| limonite | 7 | |
| graphite? | 3 | v. fine, abnt in some clasts |

Structures/Textures: conglomeratic, intraformational

Alteration: limonite

Interpretation: Intraformational conglomerate; possibly formed by slumping or other soft sediment deformation. Protolith: probably iron formation, graphitic? Siliceous clasts probably orig. chert. Probably greenschist facies metamorphism.

Additional Comments: Greenish brown layer silicate mineral probably incipient biotite (doesn't look like stilpnomelane--though that's possible)

Spec. No: 2951000277

Chip Desc: fragmental with siliceous clasts; Fe-stained

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 59 | granoblastic, in matrix and ovoidal clasts |
| biotite? | 20 | tiny, needle-like grains, brown-yellow brown pleo |
| hematite | 4 | martite |
| pyrite | 2 | |
| limonite | 15 | replacing hematite, pyrite and some biotite (or stilpnomelane) |

Structures/Textures: conglomeric, intraformational

Alteration: hematite replacing orig. magnetite; limonite replacing hematite, pyrite, and biotite

Interpretation: intraformational conglomerate; possibly formed by slumping or other soft sediment deformation. Protolith: probably iron formation? Siliceous clasts probably orig. chert. Probably greenschist facies metamorphism.

Additional Comments: "biotite" could be stilpnomelane

Spec. No: 2951000278

Chip Desc: thin layered, Fe-stained

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 20 | fine-grained, granoblastic |
| minnesotaite | 15 | light green, radiating fibers |
| stilpnomelane | 5 | reddish brown, thin fibers |
| hematite | 20 | approx. 5% is martite, remained is fine crystalline |
| limonite | 35 | much bladed, probably replacing stilpnomelane, also replacing hematite |
| pyrite | tr | |
| calcite | 5 | lines layer boundaries between qz-rich layers and Fe-rich layers |

Structures/Textures: Thin layered. Qz-rich layers crumpled into tiny crenulations. Some stilpnomelane (or limonite-replaced stilp) aligned parallel ax. pl of crenulations

Alteration: hem-lim; calcite probably secondary

Interpretation: Protolith probably iron formation. Hematite and limonite replace primary magnetite and Fe-silicates

Spec. No: 2951000

Chip Desc: conglomerate, granule-sized clasts; Fe-oxide matrix

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 50 | fine-grained granoblastic; clasts are polycrystalline |
| hematite | 25 | matrix, mostly in one half of section |
| limonite | 25 | matrix, in other half of section |

Structures/Textures: clastic, granule sized; clasts have been recrystallized so that all quartz is fine grained granoblastic

Alteration: hematite and limonite are secondary

Interpretation: Protolith probably iron formation; clasts probably originally chert

Spec. No: 2951000280

Chip Desc: red-yellow-green quartzite; colors due to lim-hem

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 70 | as clasts .5-1 mm; recrystallized into v. fine grains at boundaries; boundaries somewhat serrated |
| sericite | 15 | along grain boundaries and a couple of larger "patches" |
| limonite | 1 | replaces earlier oxides? |
| tourmaline | tr | one grain |
| unid alt min | | about 5% of grains are altered to a mix of sericite, limonite, and light brown layer silicate (incip. biot or a clay) |

Structures/Textures: clastic, sand-sized grains; a couple of sericite-rich "patches" could have been mud rip-ups. Altered clasts seem to have be very fine grained.

Alteration: sericite, limonite + unidentified light brown layer silicate alteration mineral

Interpretation: quartzite, originally a sandstone with some clay matrix and possibly clay rip-ups. Fine-grained altered clasts may have had a clayey component

Spec. No: 2951000281

Chip Desc: conglomerate or breccia? w/ "cherty" clasts, and Fe-oxide matrix

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 60 | v. fine-fine grained; prob recrystallized chert |
| hematite | 32 | appears to form a matrix |
| limonite | 5 | |
| graphite? | 3 | v. fine dissem |

Structures/Textures: clastic texture w/ rounded to angular "chert" fragments

Alteration: limonite; hematite probably secondary as well

Interpretation: probably intraformational conglomerate in iron formation

Spec. No: 2951000282

Chip Desc: lt. gray quartzite, pitted

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 80 | v. fine-grained; recrystallized chert |
| hematite | 8 | mostly as martite |
| limonite | 7 | after hematite |
| graphite | 5 | v. fine, dissem; conc. in chert clasts and defines them |

Structures/Textures: clastic, orig. fine-grained; clasts are chert granules

Alteration: hematite after primary magnetite; limonite after hem

Interpretation: Quartzite, originally a chert granule sandstone, probably derived from an iron formation

Spec. No: 2951000283

Chip Desc: conglomerate with chert clasts; hematitic

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| quartz | 72 | fine granoblastic in matrix, slightly coarser in granules |
| hematite | 15 | finely crystalline, and later cryptocrystalline |
| limonite | 5 | |
| graphite | 5 | v. fine, dissem, assoc with small cherty clasts and in matrix |
| nontronite? | 2 | lt. brown cryptocrystalline layer silicate in late veins |

Structures/Textures: clastic, conglomeratic; clasts include sand, granules, and small pebbles

Alteration: hematite and limonite; also late vein material (nontronite?)

Interpretation: clasts derived from chert, in iron formation?, probably intraformational

Spec. No: 2951000284

Chip Desc: thin layered iron formation

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 45 | fibrous in radiating clusters; some granoblastic; tiny granules in graphitic? layers have dark cores--possibly ooids? |
| hematite | 20 | massive to thin-bladed, sheaf-like |
| limonite | 5 | |
| Fe-silicate | 10 | fibrous, radiating, occurs with fibrous qz; pale greenish-brown, low mod bir. chlorite? (bir seems too low for minnesotaite) |
| graphite? | 20 | fine, occurs in dark bands w/ hematite and "oolitic?" quartz; v. low reflectance |
| pyrite | tr | |

Structures/Textures: thin bedded (2 mm thick), alternatinne layers of recrystallized chert and Fe-minerals; microfaults cutting chert layers

Alteration: hematite replaces earlier Fe-silicates; and limonite

Interpretation: iron formation, possibly graphitic

Spec. No: 2951000285

Chip Desc: light gray, fine grained, biotite-bearing metavolcanic; includes darker "patch"

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| plagioclase | 37 | short tabular grains and a couple of relict pheno's; mostly obscured by secondary mineral growth |
| chlorite | 40 | v. pale green, lt. brown interference colors |
| biotite | 5 | orange-brown pleo |
| calcite | 10 | |
| hematite | 3 | probably after magnetite |
| ilmenite | 2 | mostly altered to leucoxene |
| unid opaque | 3 | v. fine dissems; graphite? abnt in dark patch; and assoc w/ calcite |
| pyrite | tr | |

Structures/Textures: a couple of relict pheno's; texture of plag looks igneous

Alteration: Calcite is probably introduced; primary magnetite and ilmenite altered to hematite and leucoxene. Chlorite is a metamorphic mineral.

Interpretation: Protolith: intermediate volcanic--probably andesite. Uncertain as to what the darker "patch represents", as mineralogy is similar to rest of rock, except for abundance of graphite(?), which gives it the darker color. Metamorphism probably greenschist facies. Abundance of chlorite could suggest an Mg alteration.

Spec. No: 2951000286

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| plagioclase | 61 | approx. 40% as phenocrysts; remainder v. fine in matrix |
| biotite | 20 | v. fine grained, brownish green pleo; in matrix |
| chlorite | 10 | in matrix |
| apatite | 4 | long prisms |
| opaques | 5 | altered to mix of v. fine leucoxene and hematite; late limonite veins |
| quartz | tr | in matrix |

Structures/Textures: relict porphyritic texture; cut by a couple of veins with leucoxene-hem assemblage; later limonitic veins

Alteration: leucoxene-hematite alteration of ilmenite or Ti-magnetite; late limonite

Interpretation: Protolith: andesite porphyry. Greenschist facies. Alteration of Fe-Ti oxides with leucoxene-hematite forming in veins. Late limonitic veins

Spec. No: 2951000287

Chip Desc: fragmental volc.; contains one large elliptical clast

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| chlorite | 45 | pale green; brown int. colors |
| biotite | 5 | orange-brown pleo |
| calcite | 40 | forms in veins, matrix; small amount in clasts |
| qz/fspr | 7 | v. fine grained; in matrix, and in some clast matrix |
| opaques | 3 | mostly altered to leucoxene; a few are magnetite |

Structures/Textures: fragmental, probably pyroclastic; foliation probably flow banding; one large clast is amygdaloidal

Alteration: leucoxene after ilmenite; calcite introduced

Interpretation: Probably pyroclastic flow breccia; intermediate composition. Greenschist facies: assemblage chlorite-biotite-qz/fspr-cc. Calcite is introduced

Additional Comments: Is abundant chlorite related to a Mg-alteration?

Spec. No: 2951000298

Chip Desc: thin-bedded, probably iron formation

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 25 | v. fine grained |
| stilpnomelane | 52 | brown, forms v. fine-grained mats |
| minnesotaite? | 5 | colorless to pale green, slightly pleo; high bir |
| magnetite | 10 | euhedral |
| hematite | 3 | alt of magnetite, replaces some stilpnomelane |
| calcite | 5 | intergrown with stilp and minnesotaite |

Structures/Textures: thinly layered; microfault offsets layers

Alteration: hematite replacing magnetite and stilpnomelane

Interpretation: Fe-silicate-rich iron formation

Spec. No: 2951000299

Chip Desc: fragmental volcanic

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| calcite | 45 | larger grains with deformation lamellae |
| biotite | 5 | orange-brown pleo |
| chlorite | 32 | pale green |
| qz/fspr | 15 | mostly as v. fine grained matrix minerals in clasts; |
| muscovite | tr | |
| rutile? | 3 | brown, very high relief, partially altered to leucoxene |

Structures/Textures: Clastic, probably pyroclastic breccia; most clasts granule-sized. Most clasts consist of very fine qz/fspr mix

Alteration: calcite probably introduced

Interpretation: Pyroclastic breccia, dacitic or andesitic composition. Carbonate probably secondary.

Spec. No: CCW17453

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| plagioclase | 45 | euhedral to subhedral grains, sausseritized |
| hornblende | 35 | green, pleo |
| chlorite | 5 | replacing hornblende |
| epidote | 10 | mostly as sausserite; about 2% larger euhedral grains |
| sphene | 5 | 3% large blocky grains, probably pseudomorphs after ilmenite, 2% small grains assoc. w/ hornblende |
| quartz | tr | in thin shear band |

Structures/Textures: relict diabasic texture; thin shear band cuts across section

Alteration: sausserite

Interpretation: Protolith: metagabbro or diabase

Spec. No: CCW17454

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|---|
| plagioclase | 40 | mostly as remnants of tabular grains |
| biotite | 15 | brown, poorly formed, much "grades" into chlorite, appears to be related to alteration of opaque minerals |
| chlorite | 25 | pale green, weakly pleo, intergrown w/ biotite |
| kaolinite | 10 | v. finely crystalline, alt of fspr |
| opaques | 10 | mostly mix of hematite and leucoxene; prob orig both mt and ilm |
| apatite | .5 | long prisms |

Structures/Textures: Interlocking texture of plagioclase indicates an original igneous texture. Weak fol defined by biotite and chlorite; rock looks like its been subjected to shear

Alteration: kaolinite; opaques altered to hematite and leucoxene; chlorite and biotite probably related to alteration as well

Interpretation: Protolith: intermediate volcanic; appears to be somewhat sheared. Probably greenschist facies; alteration appears related.

Spec. No: CCW17456

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| quartz | 50 | V. fine granoblastic; in unsheared bands |
| hematite | 10 | in shear bands and replacing thin bladed layer silicate (minnesotaite? or possibly some stilpnomelane) |
| limonite | 20 | in shear bands |
| biotite? | 10 | fibrous, very green, pleo; mod-high bir; occurs in shear bands |
| minnesotaite? | 10 | essentially colorless tiny, radiating fibers; it may be these that are being replaced by hem/lim |

Structures/Textures: Phyllonitic; shear bands of thin fibrous mica (green biotite?), hematite and limonite. Quartz in unstrained bands is granoblastic

Alteration: hematite-limonite

Interpretation: Sheared iron formation

Additional Comments: Layer silicates are problematic. Green mineral in shear bands looks like chlorite, but is significantly birefringent. Light fibrous, colorless mica may be chlorite, however, some grains show some birefringence. It could be that most of the grains are too small to exhibit much birefringence.

Spec. No: CCW17457

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|-----------------------|
| quartz | 50 | fine, granoblastic |
| biotite | 10 | intergrown w/chlorite |
| chlorite | 37 | defines foliation |
| opaques | 3 | altered to leucoxene |

Structures/Textures: Phyllonitic; chlorite and biotite form shear bands, around lenses of quartz

Alteration: leucoxene

Interpretation: Phyllonite. Protolith uncertain--probably a metasediment, perhaps iron formation. Quartz lenses could be recrystallized chert. Quartzite lenses could also have been clasts which were flattened by shear.

Spec. No: CCW17458

Chip Desc:

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--------------------------------------|
| chlorite | 61 | very fine, pervasive |
| biotite | 20 | orange-brown pleo |
| qz/fspr | 15 | v. fine, may be mostly or all quartz |
| opaques | 4 | altered to leucoxene |

Structures/Textures: Texture is fragmental, looks possibly like a pillow breccia or agglomerate. Larger clasts seem to have rinds. One larger clast may contain a couple of amygdules.

Alteration: leucoxene

Interpretation: Probably an intermediate metavolcanic--dacite?; pillow breccia or agglomerate. Greenschist facies metamorphism. Has there been an Mg-alt to produce pervasive chlorite.

Additional Comments: The texture is not conclusively volcanic, as plagioclase is not evident, nor is there any evidence of porphyritic textures. However, matrix is so fine grained, plagioclase could be there. It may also be replaced by chlorite. Of course a volcanic rock need not be porphyritic.

Spec. No: CCW17461

Chip Desc: amphibolite

| <u>Minerals:</u> | <u>%</u> | <u>Desc.</u> |
|------------------|----------|--|
| plagioclase | 30 | tabular; light sauss |
| hornblende | 30 | green, pleo; "ophitic" texture |
| biotite | 3 | intregrown w/ hb; and in calcite vein |
| calcite | 5 | mostly in vein; also assoc. w/ epidote |
| epidote | 25 | yellow |
| sphene | 5 | mostly in fine granular masses |
| chlorite | 1 | after biotite; only in calcite vein |
| pyrite | 1 | |

Structures/Textures: relict ophitic texture; calcite vein cuts through section

Alteration: Plagioclase in one half of section is completely replaced by epidote and calcite; in the other half it is only lightly sausseritized. Calcite vein marks boundary of alteration.

Interpretation: amphibolite; probably a metagabbro or diabase; pervasive alteration of one half of section. Amphibolite facies

Spec. No: CCW17985

Chip Desc:

| Minerals: | % | Desc. |
|------------------|----------|---|
| chlorite | 65 | fibrous, pervasive |
| stilpnomelane? | 20 | thin, radiating, sheaf-like fibers; lacks birdseye |
| quartz | 5 | assoc/ w/ stilp; small isolated grains in chlorite matrix |
| pyrite | 5 | |
| ilmenite | 2 | thin blades |
| calcite | 3 | assoc. w/ pyrite and in late vein |

Structures/Textures: Appears to be a fragmental texture, masked by chlorite, especially visible under cross polars. Stilpnomelane occurs in a layer and also in what might be a matrix between clasts

Alteration: relatively unaltered except for a little late hematite altering pyrite; chlorite prob. related to metamorphis

Interpretation: Fragmental volcanic? intermediate comp? perhaps deposited within or on iron formation, with Fe-rich sediment forming a matrix.

**Appendix 295 M: Geophysical Measurements
Outcrops, Rock Dumps, Drill Core and Boulders**

1. Each sample site or drill hole is given a Project 295 file number. For outcrops there is an OTC prefix, then 295 to designate which project this work was funded under, then a sample number which is sequential for all samples measured. Rock dump samples have the prefix RD to designate their origin, then again the 295 project designation followed by the sequential sample number. For drill holes the pattern is somewhat different because the company drill hole number precedes the file number which has a DH prefix.
2. DENSITY, Density was measured on a Mettler PE 360 balance with a bridge and water filled beaker for measuring the weight in air and buoyed up weight in distilled water. Water temperature was measured and a correction made. Some samples are porous and gradually fill with water resulting in an unstable weight measurement even after a considerable time, such densities are indicated by a question mark on the reading or in the average.

3. CODE LETTER THAT EXPLAINS SAMPLE REPRESENTATION FOR AVERAGE COLUMN:

- K. Density measurements on different pieces of the same, usually dominant, lithology at the sample site described on the summary sheet.
- L. Density measurements of several sample pieces that appear to have the same lithology, but have variations in density that indicate a change in lithology or epigenetic changes of samples.

1. Each sample site or drill hole is given a Project 295 file number. For outcrops there is an OTC prefix, then 295 to designate which project this work was funded under, then a sample number which is sequential for all samples measured. Rock dump samples have the prefix RD to designate their origin, then again the 295 project designation followed by the sequential sample number. For drill holes the pattern is somewhat different because the company drill hole number precedes the file number which has a DH prefix.
2. LITHOLOGY, Brief description of sampled lithology.

MAGNETIC SUSCEPTIBILITY, The magnetic attraction of the sample as measured with an Exploranium G.S. Ltd. KT-5 magnetic susceptibility meter. Note that for readings less than ten the meter reads two places past the decimal point, for readings ten or greater than ten one place past the decimal point and for readings one hundred or greater than one-hundred it does not read a decimal fraction. Apparently sensitivity and repeatability increase at low magnetic susceptibilities.

NUMBER OF READINGS, This is the number of recorded magnetic susceptibility observations for the designated lithologic unit. Usually three observations were made for each recorded observation to eliminate erratic or anomalous observations.

3. CODE LETTER THAT EXPLAINS SAMPLE REPRESENTATION FOR AVERAGE COLUMN:

- D. One or more magnetic susceptibility measurements on separate pieces of rock from sample area described on summary sheet.
- E. One or more magnetic susceptibility measurements on separate pieces of rock. This sample is from the sample area described in the summary sheet of the first D coded sample site above this. This sample is a different lithology than the above D coded sample.
- F. One or more magnetic susceptibility measurements on a sample with one piece of rock.

PROJECT 295 OUTCROPS LOCATED IN THE FIELD OR HANNA MINING COMPANY SAMPLES OBTAINED FROM MINE PITS NOW FLOODED, DENSITY DATA:

1. Each sample site or drill hole is given a Project 295 file number. For outcrops there is an OTC prefix, then 295 to designate which project this work was funded under, then a sample number which is sequential for all samples measured. Rock dump samples have the prefix RD to designate their origin, then again the 295 project designation followed by the sequential sample number. For drill holes the pattern is somewhat different because the company drill hole number precedes the file number which has a DH prefix.
 2. **DENSITY**, Density was measured on a Mettler PE 360 balance with a bridge and water filled beaker for measuring the weight in air and buoyed up weight in distilled water. Water temperature was measured and a correction made. Some samples are porous and gradually fill with water resulting in an unstable weight measurement even after a considerable time, such densities are indicated by a question mark on the reading or in the average.
3. CODE LETTER THAT EXPLAINS SAMPLE REPRESENTATION FOR AVERAGE COLUMN:
- G. One or more density measurements on separate pieces of sample which are the same lithology as determined from visual and density criteria, (there might be questions about the 2.49 and 2.90 gm/cm³ measurements from area eight). The sample is from the sample site described on the summary sheet.
 - H. One or more density measurements on separate pieces of sample. This sample is from the sample area described in the summary sheet of the first G coded sample site above this. This sample is a different lithology than the above G coded sample.

PROJECT 295 BOULDER SAMPLES FROM GLACIAL DEPOSITS, USUALLY GRAVEL PITS, DENSITY DATA:

1. DEPTH IN FEET, Down hole depth or core interval where geophysical measurements were taken.

LITHOLOGY, Brief description of sampled lithology.

MAGNETIC SUSCEPTIBILITY, The magnetic attraction of the drill core as measured with an Exploranium G.S. Ltd. KT-5 magnetic susceptibility meter. Note that for readings less than ten the meter reads two places past the decimal point, for readings ten or greater than ten one place past the decimal point and for readings one hundred or greater than one-hundred it does not read a decimal fraction. Apparently sensitivity and repeatability increase at low magnetic susceptibilities.

NUMBER OF READINGS, This is the number of recorded magnetic susceptibility observations for the designated lithologic unit. Usually three observations were made for each recorded observation to eliminate erratic or anomalous observations.

PERCENT METER COVERED, In many places there was not enough core to cover the whole face of the meter therefore we include an estimate of the percentage of the meter face covered, a more accurate susceptibility can be extrapolated from this information.

DENSITY, Density was measured on a Mettler PE 360 balance with a bridge and water filled beaker for measuring the weight in air and buoyed up weight in distilled water. Water temperature was measured and a correction made. Some samples are porous and gradually fill with water resulting in an unstable weight measurement even after a considerable time, such densities are indicated by a question mark on the reading or in the average.

NUMBER OF READINGS, This is the number of recorded density observations for the designated lithologic unit.

2. Each sample site or drill hole is given a Project 295 file number. For outcrops there is an OTC prefix, then 295 to designate which project this work was funded under, then a sample number which is sequential for all samples measured. Rock dump samples have the prefix RD to designate their origin, then again the 295 project designation followed by the sequential sample number. For drill holes the pattern is somewhat different because the company drill hole number precedes the file number which has a DH prefix.

1. DEPTH IN FEET, Down hole depth or core interval where geophysical measurements were taken.

LITHOLOGY, Brief description of sampled lithology.

MAGNETIC SUSCEPTIBILITY, The magnetic attraction of the drill core as measured with an Exploranium G.S. Ltd. KT-5 magnetic susceptibility meter. Note that for readings less than ten the meter reads two places past the decimal point, for readings ten or greater than ten one place past the decimal point and for readings one hundred or greater than one-hundred it does not read a decimal fraction. Apparently sensitivity and repeatability increase at low magnetic susceptibilities.

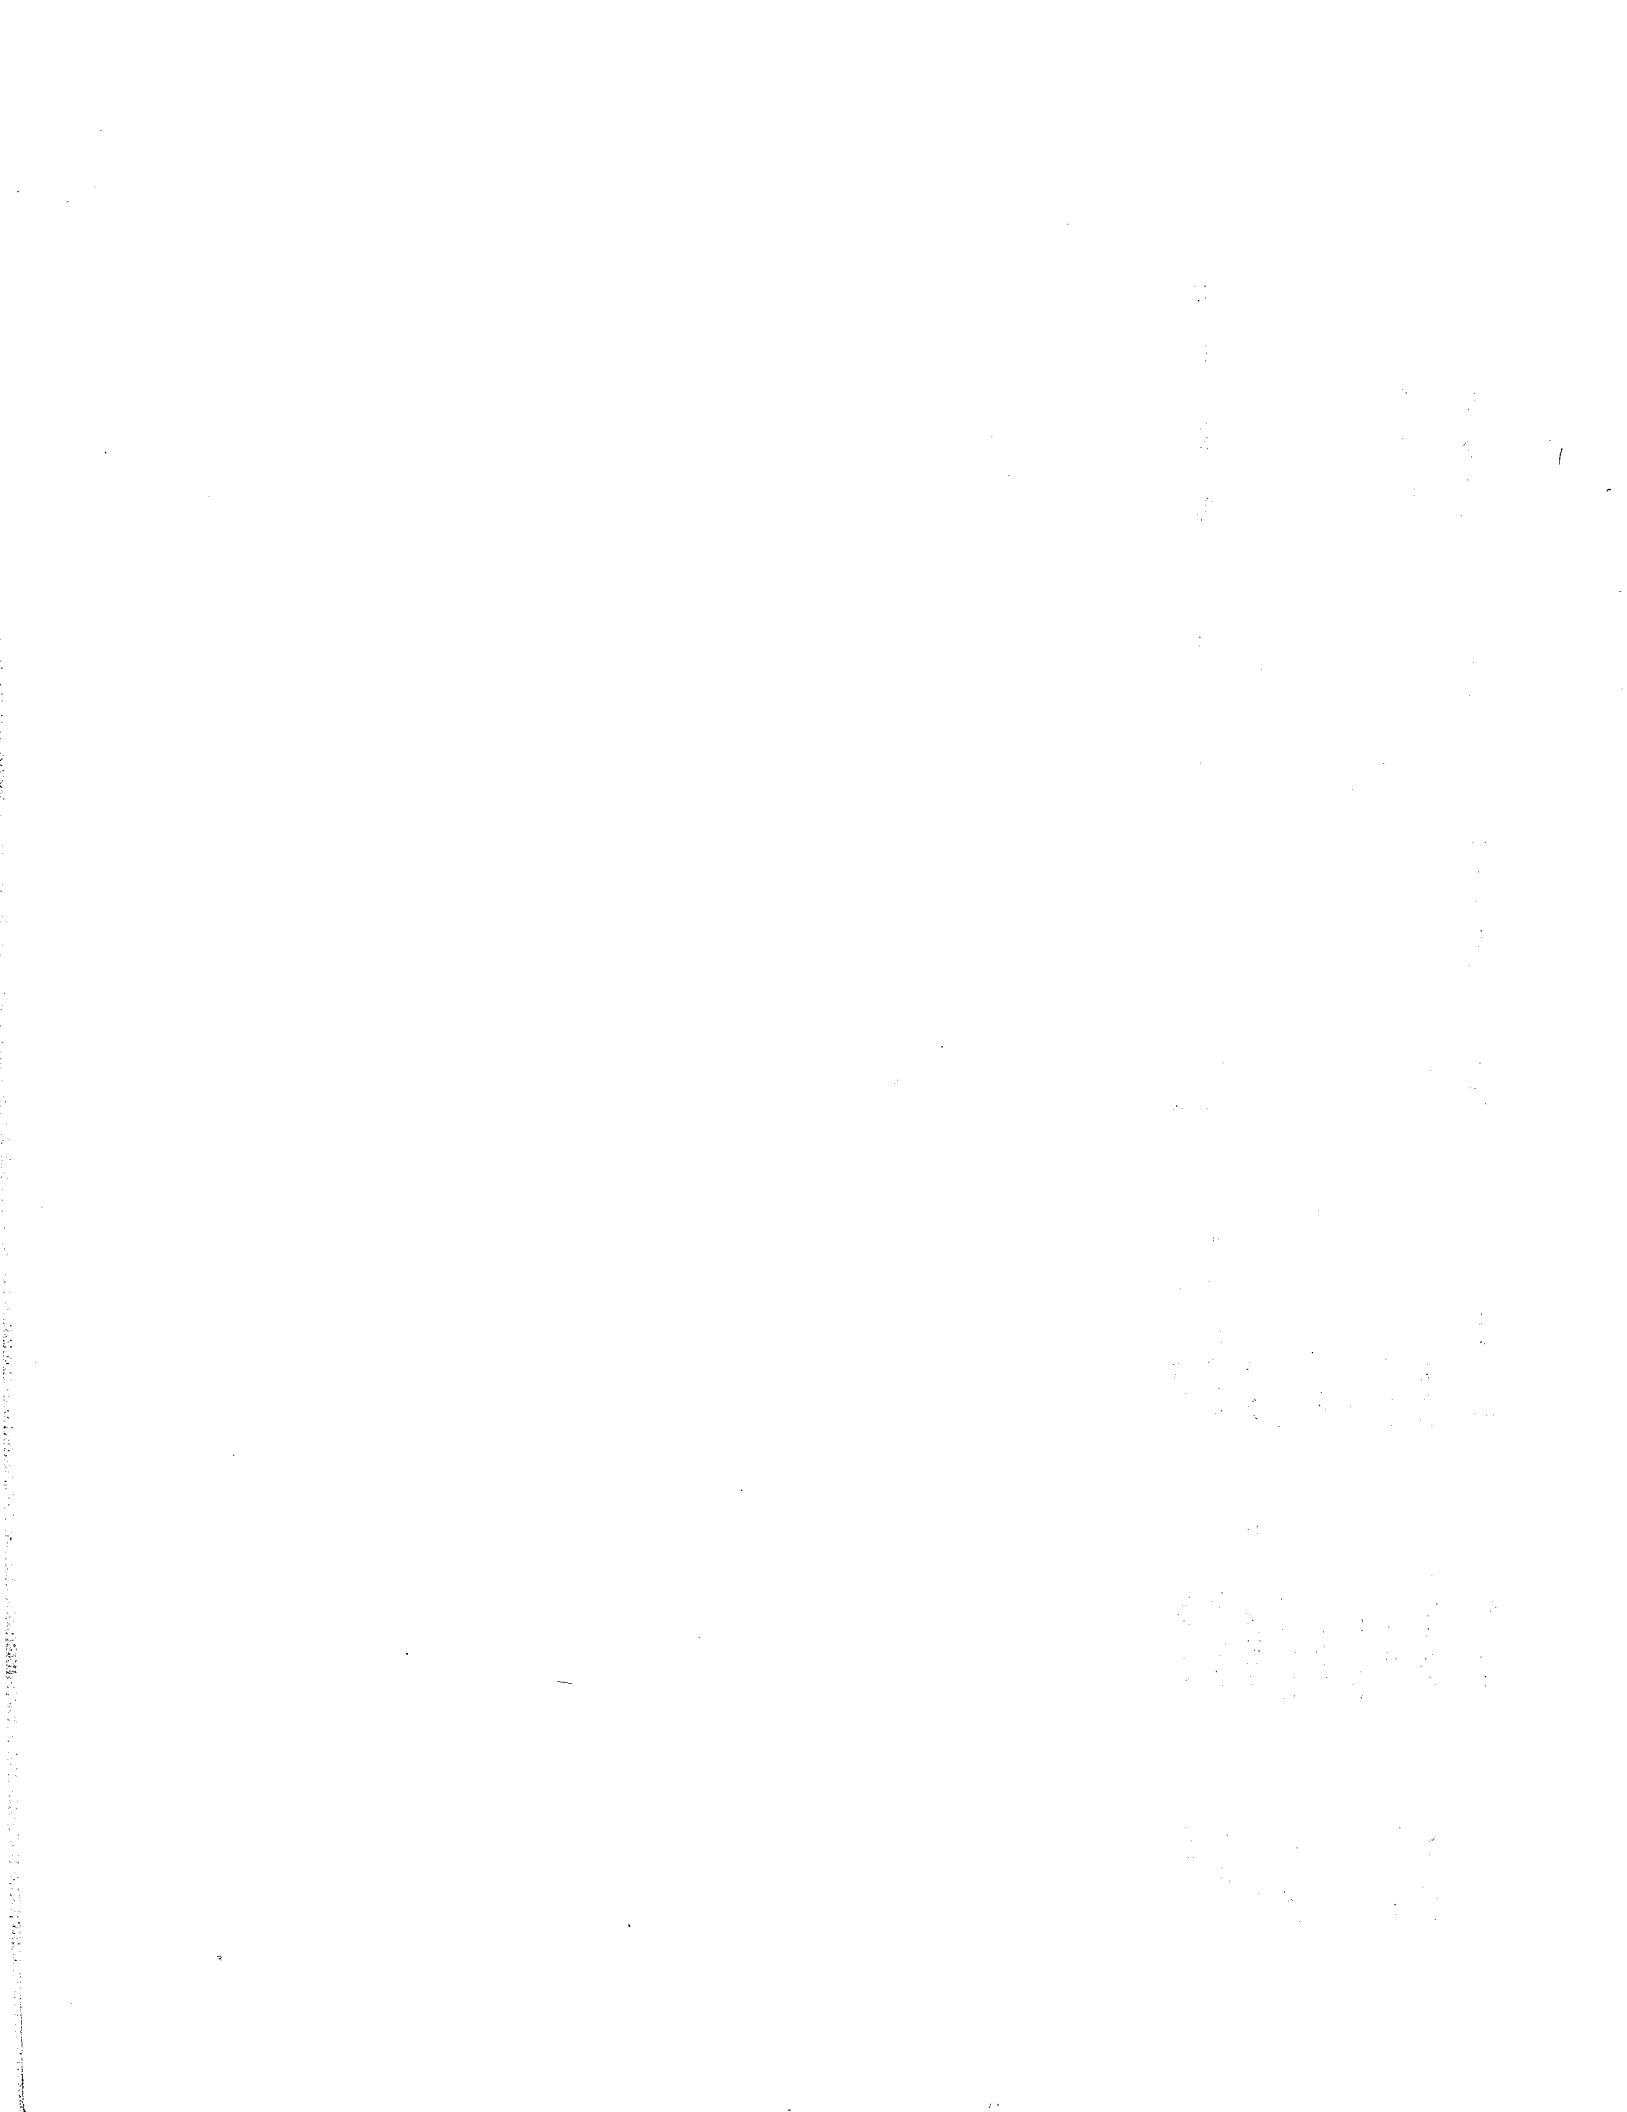

NUMBER OF READINGS, This is the number of recorded magnetic susceptibility observations for the designated lithologic unit. Usually three observations were made for each recorded observation to eliminate erratic or anomalous observations.

PERCENT METER COVERED, In many places there was not enough core to cover the whole face of the meter therefore we include an estimate of the percentage of the meter face covered, a more accurate susceptibility can be extrapolated from this information.

DENSITY, Density was measured on a Mettler PE 360 balance with a bridge and water filled beaker for measuring the weight in air and buoyed up weight in distilled water. Water temperature was measured and a correction made. Some samples are porous and gradually fill with water resulting in an unstable weight measurement even after a considerable time, such densities are indicated by a question mark on the reading or in the average.

NUMBER OF READINGS, This is the number of recorded density observations for the designated lithologic unit.
