Reports 255-1, 265, 266

ADDENDUM, ERRATA

Page i. Special thanks should be given to Leon Gladen whose interest in mineralization of the "Copper Fault" resulted in the initiation of Project 265.

Page 23. An example of the logger (Rock Ware, Inc.) drill hole profiles, is included in the report. The remaining "Logger" drill hole profiles were not completed at the time of printing; however, they will be available from the MnDNR office in Hibbing by August 1, 1989. Please note that the coding may not be exactly the same as those used in Report 255, due to use of an upgraded version of the original Logger program.

Pages 10-15. Table 255-1-2 lists drill holes from both Report 255-1 and the earlier Report 255 (Dahlberg, 1987) having anomalous Pt+Pd+Au values.

Page 17. Table 3A, under Analytical Work, (not 2A) describes the analytical package used for Duluth Complex mafic-ultramafic rocks, and Table 3B the package used for Duluth Complex granitoid rocks.

Page 139. The statement "This data is on file at the Soudan Mine State Park, USX Corporation, Minnesota DNR Minerals Division, and Ironworld U.S.A." should read "The original sources of data included the Soudan Mine State Park, USX Corporation, Minnesota DNR Minerals Division, and Ironworld U.S.A.

Page 141. Additional analyses for Soudan Mine samples collected during the excavation of the University of Minnesota Physics Experiment room can be found in the publication "Analytical Results of the Public Geologic Sample Program, 1985-1987 Biennium" by Morey, G. B. and McDonald, L. L. (1987), Minnesota Geological Survey Information Circular 25, 59 pages.

Page 246. Second Column. The statement "The analyses to be performed were generalized into the following groups:" should read "The analyses performed were generalized into the following groups:".

Also, some of the analytical groups were listed incorrectly. The correct elemental listing within these groupings are as follows:

BASE METALS (BM) - include Co, Ni, Cu, Zn, Pb

TRACE ELEMENTS (TE) - includes Li, Be, B, C, F, Cl, V, Cr, Ga, Ge, As, Se, Br, Rb, Sr, Zr, Nb, Mo, Cd, In, Sn, Sb, Te, I, Cs, Ba, Hf, Ta, W, Hg, Tl, Bi

MAFIC SPINEL OXIDES (MSO) - includes the elements or their oxides of Mg, Ti, V, Cr, Mn, Fe

The other groups are listed correctly.

A Minerals Diversification Project

1989

Reports 255-1
265, 266

This report is on file at various major libraries in Minnesota. It may be purchased at the Hibbing office, DNR Minerals Division. For further information contact Richard Ruhanen at (218) 262-6767

ACKNOWLEDGEMENTS

These three studies constitute a segment of the Minnesota Mineral Diversification Plan which was made possible through legislative funding by the Minnesota Minerals Coordinating Committee.

The efforts of the following people made these projects possible in the contexts shown below.

Sue Saban, Helen Koslucher, Coleen Keppel, and Diane Williams provided the extra hours needed to get the job done as far as word processing, desktop publishing, LASER printing, bookkeeping, and logistical support. Rick Ruhanen provided and coordinated computer support for the projects. Jacki Jiran provided most of the computer support and spent extra hours coordinating the desktop publishing. Tom Anderson kept machinery and vehicles functioning when they were needed. Dave Dahl, Pat Geiselman, and Jay Niebuhr (especially) contriubuted toward the artwork. Greg Walsh and Jay Niebuhr drafted figures and plates. Pat Geiselman, Dawn Needeham, Mike Ellett, and Jim Strommer all sawed and moved drill core. Jim Strommer and Dawn Needeham contributed to the rock descriptions, and to the task of data gathering. Mike Lubotina and Al Dzuck for assembling metal shelving at below zero temperatures at the Soudan Mine core storage site. Mike McKenna and Henk Dahlberg for critically reading this manuscript.

Special thanks for Frederick L. Klinger, and Richard G. Kendall, for providung copies of their respective theses on the Soudan Mine.

Special thanks to Cedric L. Iverson for fruitful discussions, and for finding missing information about the Soudan Mine drilling.

The people of the Parks Division of the Minnesota Department of Natural Resources need special acknowledgement for their cooperation in making the Soudan Mine core available. This includes Paul Wannarka, Acting Park Manager and the entire, helpful staff of the Soudan Mine State Park.

This volume is dedicated to the late Don Logan, Park Manager of Soudan Mine State Park. His zeal toward underground mine history, and educating the public on this important fragment of Minnesota's past and future, made the Soudan Mine sampling possible.

ABSTRACT

These 3 projects sampled and analyzed pre-existing drill core, with an emphasis on precious metals and elements which had previously been neglected.

Project 255-1 sampled a total of 512 samples from the basal contact and inner portions of the largely mafic Duluth Complex in northeast Minnesota. The widespread nature of the mineralization associated with the basal contact portion was confirmed with 3 drill holes containing combined Au + Pt + Pd values exceeding 1000ppb and 13 other holes with lesser mineralization. Drill holes from the inner portion exhibited lower values.

Project 265 sampled 251 samples from 25 development drill holes from the Soudan Mine (Algoman-type iron formation). Gold mineralization (several hundred ppb's) appears to be breccia related. Pt and Pd values of similar values are problematical. Other samples exhibited anomalous Ba and F.

Project 266 analyzed 213 samples from 12 drill holes located in the granite-greenstone terrane of north central Minnesota (Beltrami County). Gold mineralization over 1 ppm was confirmed from previous sampling, and appeared to be associated with Bi, As, Sb, Se, S, Ag, Cu, Mo and Fe_2O_3. A weakly mineralized drill hole contained a small interval of calcareous "blackschist" alteration rock.

Samples were analyzed for (varied with project) Au, Pt, Pd, Bi, Sb, As, B, Ba, S, Se, Te, Ag, Cu, Ni, Mo, W, Sn, F, Ga, Sc, Y, La, Ce, Zr, Nb, Ta, Cd, Zn, Pb, Cr, Co, V, TiO_2, MgO, Fe_2O_3, MnO, SiO_2, Al_2O_3, P_2O_5, Li, Na_2O, K_2O, Rb, Sr, CaO, Be, Cs, and Cl.

INTRODUCTION

The Hibbing Drill Core Repository (Library) contains over 685,000 actual feet of drill core and over 265,000 drilling feet of cuttings from approximately 4,200 drill holes. Most of these have been drilled by private mineral exploration companies during the course of exploration for iron ore, uranium, base metals and/or precious metals. Other drill holes are from government agencies such as the U.S. Geological Survey, U.S. Bureau of Mines, Minnesota Geological Survey, Minnesota Department of Natural Resources and Minnesota Department of Transportation.

Two separate projects have been conducted on core from this repository. One, a continuing project (255-1), focuses on the magmatic rocks of the Duluth Complex in northeastern Minnesota, and the other involves the Archean Greenstone belt rocks (266) in north-central Minnesota.

A third project (265) evaluated drill core from the original development drilling for the former U.S Steel Soudan Mine (now the Soudan Mine State Park). No other parcel of Archean Greenstone in Minnesota has so much available drilling information.

Each of these projects will be covered as separate sections within this report.

DULUTH COMPLEX SAMPLING PROJECT

ABSTRACT

This continuing project analyzed 373 samples from 17 drill holes located in the basal contact zone of the Duluth Complex, and 139 samples from 17 drill holes located in the inner portion of the Duluth Complex. The drill holes are maintained at the Department of Natural Resources, Mineral Division's Core Library in Hibbing, MN.

Drill holes NM-3, DU-13, and W-12 all had combined Pt + Pd + Au values greater than 1000 ppb, with 13 other drill holes containing lesser mineralization. This continues to verify the widespread nature of this mineralization in the basal contact zone of the Duluth Complex.

The analyses from the drill holes of the inner portion exhibited lower values.

Samples were analyzed for Pt, Pd, Au, Ag, S, Cl, F, Cu, Ni, Cr, Co, Zn, TiO2, V, Rb, Cs, Sr, MgO, Fe2O3, SiO2, Bi, As, Sb, Se, Te, Sc, Y, Zr, Al2O3, CaO, Na2O, K2O, MnO, and P2O5.

INTRODUCTION

The main purposes of this mineral potential project are to:

1) sample pre-existing drill core in order to characterize previously unrecognized platinum group element and associated mineralization and related alteration

2) to describe the lithologic framework of the samples.

Most drill holes and previous sampling of the Proterozoic Duluth Complex have been located along the footwall where the Complex has intruded older Proterozoic and Archean rocks. As a follow-up to Project 255 (Dahlberg, 1987), this project has described and analyzed 372 samples from 17 drill holes located in proximity to the footwall of the Duluth Complex. Additionally, 139 samples were taken from 17 drill holes located in the inner portions of the Duluth Complex. Mafic and felsic samples were analyzed using slightly different analytical packages.

DULUTH COMPLEX LOCATION, LAND OWNERSHIP AND GENERAL ACCESSIBILITY

The Duluth Complex is a series of intrusive rocks located in Northeast Minnesota which comprises an area of about 2,500 square miles. The outcrop pattern is arcuate in shape and extends from Duluth in the south to nearly the northeastern tip of Minnesota (Phinney, 1972).

Ground access in the Duluth Complex is problematic due to the variable road density. Swampy conditions in many areas require the use of winter trails for drill rigs or other heavy equipment. Portions of the Duluth Complex, however, do have relatively good, but uneven, outcrop coverage.

Approximately 55% of the land occupied by the Duluth Complex is owned by the Federal government (more so to the north), with about 25% under State and County jurisdiction, and 20% under private ownership. Private mineral exploration companies currently hold leases on approximately 16,500 acres of State of Minnesota lands in the Duluth Complex.

SUMMARY GEOLOGY OF THE DULUTH COMPLEX

A series of mafic igneous rocks (both intrusive and extrusive), known from outcrop or inferred from geophysical data, forms an arc that runs from Kansas, through Iowa, Minnesota and Lake Superior, then south through Michigan and possibly into Ohio. This Middle Proterozoic feature is known as the Midcontinent Rift System. Keweenawan extrusive and intrusive igneous and sedimentary rocks in northeastern Minnesota are a result of the abortive rifting episode which caused the development of this Rift System (Holst, et al., 1986) within the older Archean granite-greenstone and Early Proterozoic sediments. The dominantly-mafic extrusive rocks of the North Shore Volcanic Group are intruded by the rocks of the Duluth Complex (largely at the unconformity between the North Shore Volcanics and the older rock sequence). The North Shore Volcanics are overlain by clastic sedimentary rocks associated with the rifting.

The Duluth Complex is a large body of dominantly mafic intrusive igneous rock that occurs in an arcuate pattern from Duluth, Minnesota, north to very near the United States-Canada border, and nearly to Lake Superior in the east. It consists of a series of intrusions of diverse composition that can be grouped roughly into an early series of anorthosites, gabbroic anorthosites, and a later troctolitic series (Holst, et al., 1986). Other lesser rock types include ultramafics, ferrogranodiorites, granites (often granophyric), and hornfels contaminated rocks.

The contacts between intrusions are usually not exposed, but geophysics, i.e. second vertical derivative filtered magnetics and gravity (Chandler, in Holst, et al., 1987) enable deduction of their location where outcrop is lacking.

Many studies have been conducted on various aspects of the geology of the Keweenawan igneous rocks in Minnesota. Publications by Weiblen and Morey (1980), Weiblen (1982), and Green (1982, 1983) provide useful summaries on the geology of Keweenawan igneous rocks. Recent papers such as Holst, et al.,(1986) and Severson (1989), further elucidate the internal structure and stratigraphy of the Duluth Complex.

Copper-nickel mineralization has spurred past drilling in the Duluth Complex. This drilling focused on the footwall contact rocks, where the Duluth Complex intruded the older Archean greenstone granites, Early Proterozoic Biwabik Iron Formation and the sedimentary Virginia Formation.

EXPLORATION HISTORY OF THE DULUTH COMPLEX

Numerous occurrences of mineralization within the Duluth Complex have been reported since the mid-1800's. These minerals included titaniferous magnetite, chromite, copper sulfides, ilmenite, apatite, graphite, nickel sulfides, and more recently platinum group elements (Martin, 1985).

The outcrop discovery of copper-nickel sulfides in the early 1950's lead to extensive drilling of portions of the Duluth Complex footwall. Exploration for sulfides, titaniferous magnetites and metamorphosed iron formation, has produced over 6,000 drill holes. Papers concerning the more general sulfide mineralization include Foose and Weiblen (1972), Tyson and Chang (1984), Bonnichsen (1972), Bonnichsen (1974), Bonnichsen, Fukui and Chang (1980), Mainwaring and Naldrett (1977), Pasteris (1984), Ripley and Al-Jassar (1987) and Ervin (1988).

At one point, conditions were encouraging enough for Amax to complete an exploration shaft; however, an economic downturn forced cancellation of the project. Some precious metal evaluation was carried out along with the copper nickel work, but serious interest in the platinum group element potential was not renewed until the mid-1980's [Sabelin (1985), Sabelin (1987), Jongewaard (1986) and Dahlberg (1987)].

METHODOLOGY OF CORE LOGGING AND SAMPLING

All drill logs, analytical results, and other data were placed in open file for public examination on a monthly basis as they were received. This included the duplicate and standard sample analyses.

Seventeen drill holes were logged and sampled in both the basal contact portion and the inner portions of the Duluth Complex (a total of 34 holes). A summary of the logging and sampling is shown in Table 255-1-1A and Table 255-1-1B (WR-1 refers to the gabrroic analytical package, and WR-2 refers to the granitic analytical package; see Tables 255-1-3A and 255-1-3B).

Logging and Sampling Procedures

The systematics of the procedure used for logging and selecting sample intervals and the location of thin sections and polished thin sections was as follows:

1. Lay out as much of the drill core as was possible.

2. Make a visual inspection of the core, from top to bottom, and use a piece of chalk to write down on the core:
   a. rock types;
   b. contacts between rock types;
   c. the presence of sulfides (esp. chalcopyrite and bornite);
   d. lamination/foliation of minerals;
   e. cumulate zones;
   f. dikes;
   g. uncommon minerals (e.g.: tourmaline, calcite, zircon, sphene, muscovite, apatite + problematics...);
   h. pegmatoidal stretches;
   i. oxide minerals (is it magnetite, ilmenite or chromite?);
   j. alteration (serpentinization, diseased plagioclase, uralitization, chlorite...);
   k. rusty-red fluid drops on core;
   l. mixed rocks, contamination, homogenization;
   m. inclusions; and
   n. graphitic zones.

3. The next step was to go back to the top of the section that was layed out and use all the information that was written on the core to take a detailed look at those portions which had some of the criteria for possible presence of Platinum Group Element (PGE) mineralization.

4. Intervals were then selected for sampling (every attempt was made to sample 10' intervals). The core above and below, as well as the sample intervals were then logged.

5. Approximately 20' of the lowest portion of the logged drill core would be left out while the next portion of the hole was examined and logged.

Sampling Criteria

The criteria listed below were used to determine which intervals were to be sampled. Sulfide minerals were found in nearly all intervals that were sampled. Table 255-1-2 lists those criteria used along with short lithologic descriptions of those drill holes containing anomalous values of Pt + Pd + Au.

1. Pegmatitic textures.

2. Oxide cumulate zones, for possible chromite.

TABLE 255-1-2F

3. Mixed rocks, (especially anorthositic portions mixed with troctolitic to picritic rocks).

4. Inclusion-rich portions, (esp. cordierite-hornfels inclusions and zones w/contamination of the igneous rock by assimilation of pelitic hornfels).

5. Semi-massive to massive sulfide zones, (usually pyrrhotite).

6. Graphite intergrown w/sulfides, oxides, or silicates.

7. Zones with diseased or bleached plagioclase.

8. Contact zones between thick anorthositic to gabbroic units and troctolitic or picritic units.

These eight criteria were the main focus of the sampling, but there were also other types of rocks sampled. These included:

1. Copper sulfide bearing granitic dikes or footwall granites with copper sulfide.

2. Thin pyroxenite dikes in the footwall rocks.

3. Serpentinized rocks, highly uralitized gabbros, and diorite dikes.

4. Picrites with rusty-red fluid drops.

Appendix A contains a listing of the sample numbers, drill holes, footages, and lithologic descriptions. Note: the intervals that end in "0" feet indicate that the samples were taken for thin sections, polished thin sections or other miscellaneous information; also note that the list of abbreviations used in the lithologic descriptions is at the beginning of Appendix A.

Appendix B is a listing of the type of analysis and also contains information about the locations of the drill holes.

SAMPLE PREPARATION AND ANALYSIS

The sample preparation and analytical work went out on bid, and Technical Service Laboratories, Ltd., of Mississauga, Ontario, was the low bidder.

Sample Preparation

Samples were crushed in a jaw crusher to 1/4 inch, followed by a cone crusher to 1/10 inch. Each sample was then split and a 1/2 pound portion was pulverized to -150 mesh in a shatter box.

Analytical Work

Table 255-1-3A and 255-1-3B (corresponding to WR-1 and WR-2 respectively) describe the analytical packages used for Duluth Complex rocks. Table 2A describes the analytical package used for Duluth Complex Mafic-Ultramafic rocks. This table indicates the elements (and some oxides) analyzed, the detection limits, the sample weight used, the analytical method, and the overlimit values. The overlimit value refers to the highest analytical value for which quality results can be produced for a given analytical method and element.

The following abbreviations are used for both Tables 3A and 3B:

% = percent (parts per hundred)

PPM = parts per million

PPB = parts per billion

FA = fire assay

ICP = inductively coupled plasma emission spectrometry

AA = atomic absorption

SP ION EL = specific ion electrode

WR = whole rock (inductively coupled argon plasma emission spectrometry)

INAA = instrumental neutron activation analysis

One requirement stipulated for TSL was that the precious metals Au, Pt, and Pd be analyzed using as much sample as is necessary to provide good analytical numbers.

Other procedures used with whole rock (WR) analyses include the following:

Fusion

Each gram sample was fused with a flux mixture of lithium carbonate and boric acid. Each fusion was carried out in a graphite crucible using a proprietary procedure.

Sample Dissolution

The molten sample and flux mixture were poured directly into a nitric acid solution contained in a plastic bottle. The molten slag shatters on impact and as a result, dissolves quite readily. Each bottle was then placed on a shaker for 4 hours to ensure complete dissolution.

Internal Standard

After dissolution, each sample solution was diluted with water containing an internal standard. All dilutions used in this procedure were made to a constant or recorded weight. The

samples were mixed and a portion filtered prior to analysis on the ICAP.

<u>*Standardization*</u>

An individual standardization is carried out by using five international standard samples. These samples have been obtained from the Canadian Certified Reference Material Project, United States Geological Survey, National Bureau of Standards (USA), Centre De Recherches Petrographics Et Geochemiques (France) and the National Institute for Metallurgy (South Africa). Standard samples are treated in the same manner as are samples. In the event that a sample is outside the range of standards used (ie. a limestone in with silicate rocks samples,) this sample is rerun on the ICAP with appropriate standards. Solution standards mean that samples with extremes of one element can be accommodated by the addition of that element in solution to appropriate standards. TSL has a standard group of approximately 35 standards that can be used as a routine. Standardization for the secondary elements (Zr, Sr, Ba, Sc, Y) is carried out in much the same manner in that known reference materials are used to control the analysis.

For ICP or AA work, a multi- acid digestion was used. For each sample, 1.0 gram of pulp was treated with a combination of HF, HClO4, HNO3 and HCl. Samples were digested, taken to HClO4 fumes, diluted and analyzed by ICP or AA as required.

Instrumental Neutron Activation Analysis (INAA) was performed by Activation Laboratories, Ltd. Activation Laboratories, Ltd. is a joint venture company owned by Technical Service Laboratories and Dr. Eric Hoffman.

In order to use selenium effectively as a geochemical indicator in many materials, a lower detection limit is needed. A detection limit of 5 ppb was requested, but TSL was only capable of a detection limit of 50 ppb using 1 gram samples and hydride ICP equipment.

Analytical results were made open file to the public on a monthly basis as they were received. This includes the duplicate and standard sample analyses.

Duplicate and Standard Samples

During the course of analytical work, 5 samples that had been previously analyzed, and 2 samples of USGS standard STC-1 (troctolite cumulate) were submitted to TSL for analysis. The results are shown in Tables 255-1-4A and 255-1-4B. The previous analysis of the 5 samples was done by X-Ray Laboratory of Don Mills, Ontario.

The precious metal values, while not necessarily in good agreement, are not worrisome either. The values are in broad agreement and both labs have evidently not missed the low to medium amounts of mineralization that the samples appear to possess. Results vary with the elements or oxide (e.g. fluorine) analyses by TSL are consistently higher than the analyses by X-Ray lab.

TABLE 255-1-4b

DESCRIPTION AND DISCUSSION OF RESULTS

Basal Contact Zone of the Duluth Complex

A summary of the anomalous precious metal values (Pt + Pd + Au) in the drill holes is shown in Table 255-1-5. This table places the anomalous values into groups, and indicates the total footages containing those values. Drill holes with anomalous values are also shown on Plate 1.

Also "Logger" (Rockware, Inc.) profiles of anomalous drill holes are included in the map pocket at the end of the reports.

Tables 255-1-6 and 255-1-7 list the mafic and granitic analytical results for the 17 drill holes from the contact zone of the Duluth Complex. (All mafic and all granitoid analytical results are also contained in Appendices C and D.) Figures 255-1-1 and 255-1-2 are similarly the mafic and granitoid sample number vs. sample value number plots which correspond to these tables.

Note: These figures use the same number value scales as Figures 255-1-3 and 255-1-4, so that the inner and contact portions can be directly compared between figures.

Drill holes in Table 255-1-6 that have anomalous precious metal values are MV2-1W, DU-7, NM-3, DU-13, D-6A, BA-4, W-12, BA-3, B-3, W-5, A-2, A-4, A-1, 3, CN-1, and CN-7. Elements that exhibit "bumps" which may be spatially related to Pt, Pd, and Au include (specific ones depend on drill hole) Ag, Cu, Ni, Co, Zn, Cr, Cl, Ba, Sr, Te, As, Al_2O_3, Na_2O, and K_2O. The anomalous CN-1 sample appears to be related to a drastic decrease (moving downhole) in V, TiO_2, Zn and Cl.

For the granitoid analyses of the basal part of the complex, the only precious metal with assay values above the detection limit was palladium. Trends are very hard to discern (see Figure 255-1-2).

Inner Zone of the Duluth Complex

Tables 255-1-8 and 255-1-9 list the mafic and granitoid analyses respectively for the 17 drill holes in the inner zone of the Duluth Complex. Figures 255-1-3 and 255-1-4 are similarly the mafic and granitoid sample number vs. sample value plots which correspond to these tables.

Note: These figures use the same number value scale as Figures 255-1-1 and 255-1-2 so that the contact and inner portions can be directly compared (Figure 255-1-1 to Figure 255-1-3, and Figure 255-1-2 to Figure 4).

Drill hole numbers: NR-1, G-4, G-3, and G-6 have some elevated Pt + Pd + Au values; however, compared with the contact zone of the Duluth Complex, the values are rather small. Other elevated values are Cr in DDH NE-2; F in DDH's G-6 and SE-1; TiO_2 in DDH's SR-1 and S-1; V in DDH's SR-1 and NR-1; Rb in DDH's G-3 and G-6; Cs in DDH BL-1; and Zr in DDH's G-5, G-4, G-3, and G-6.

It appears that the DDH's G-3 and G-6 have relatively more elevated values than the remaining holes in the inner portion of the Duluth Complex.

DDH's G-3 and G-6 are located in gabbro and ferrogabbro (mostly olivine-bearing) according to DNR Project 203-A, "Duluth Complex Geology, a DNR Internal Compilation".

CN-1	220' (59%)	10' (3%)	10' (3%)			310'	65%
CN-7	160' (35%)	30' (7%)				460'	42%

NOTE:

FOOTAGES = NUMBER OF FEET WITH ASSAY VALUES WITHIN GIVEN RANGE (ppb)
PERCENT = NUMBER OF ANOMALOUS FEET / NUMBER OF FEET SAMPLED PER GIVEN DDH

TABLE 255-1-5

From Figure 255-1-3, the elements that may have "bumps" which may be spatially related to precious metal "bumps" are: Cl, Zn, TiO_2, V, Zn, F, Cu, Ni, Sc, MgO, K_2O, Zr, MnO, Se, and Te. From Figure 255-1-4, the small number of samples of granitoid rocks make it difficult to make any kind of generalizations.

DDH NE-2, with a relatively high Cr content, is located to the northeast of the "Snake" anomaly. The olivine in this drill core at 302' was characterized as being relatively primitive for the Duluth Complex (Green, 1986).

TABLE 255-1-9

MINERALOGICAL STUDIES

Project work on Duluth Complex rocks included mineralogical studies which followed several different avenues.

Apatite Studies

A microprobe study on apatite grains from 5 drill holes was carried out in order to compare Duluth Complex apatites with apatites from other intrusions. Alan E. Boudreau from the University of Washington performed the analyses, with the results given in Table 255-1-10, and they are also plotted in Figure 255-1-5 on an F-Cl-OH ternary diagram (along with values for other intrusions (after Boudreau and others, 1986)). Please note that for the Rare Earth Elements (REE), the detection limits were about 0.05 wt%, hence the La values are particularly subject to error. The OH and H2O were calculated by anion site difference (OH + F + Cl = 1 pfu). The depths of the samples were 394' for D-10, 1334.8' for D-5, 945.4' for SE-1, 48' for NE-2, and 2581.1' for BA-2.

The chemistry for the apatites for DDH's D-10 and S-5 were very similar. The Cl concentrations were high compared with the Skaergaard or Kiglapait intrusion non-cumulus apatites, but are low compared to the chloroapatites which predominate in the lower 1/3 of the Stillwater intrusion. Boudreau reported that the halogens were not appreciably zoned.

The samples from SE-1 had very high REE contents, with values comparable to the J-M reef of the Stillwater Complex (Boudreau, 1986). Values from BA-2 were also somewhat high.

SEM/EDS WORK

A number of samples were submitted to the M.A. Hanna Research Center in Nashwauk, Minnesota for electron microscopy work (SEM/EDS) or X-ray diffraction (XRD). Figures 255-1-6, 255-1-7, and 255-1-8 contain SEM images and EDS spectra for samples 20043, 20310, and 20311. These samples raised questions about their being spinels/ilmenite/chromite.

Sample 20043 (DDH CN-1, 650') was dominantly rounded hypersthene grains "floating" in a pyrrhotite matrix, with accessory biotite, amphibole, serpentine, olivine (?), and pyrite.

Sample 20310 (DDH CN-1, 812') was dominantly rounded olivine (hortonolite (?) Fo 45-50) grains "floating" in a pyrrhotite matrix, with minor to trace amounts of hypersthene, serpentine, chalcopyrite, pentlandite, and pyrite (?).

Sample 20311 (DDH CN-1, 799.2') was intergrown hypersthene and pyrrhotite. Considerable pyrrhotite was included in the hypersthene. One bytownite grain was observed.

Other identifications answered the following questions:

Sample CL 20312 (DDH Du-13, 529') *Are these fluorite crystals?* "Fluorite" crystals turned out to be apophyllite crystals occurring in a calcite lined vug.

Sample CL 20313 (DDH Du-13, 515') *Are these "zircons intergrown with tourmaline"?* These

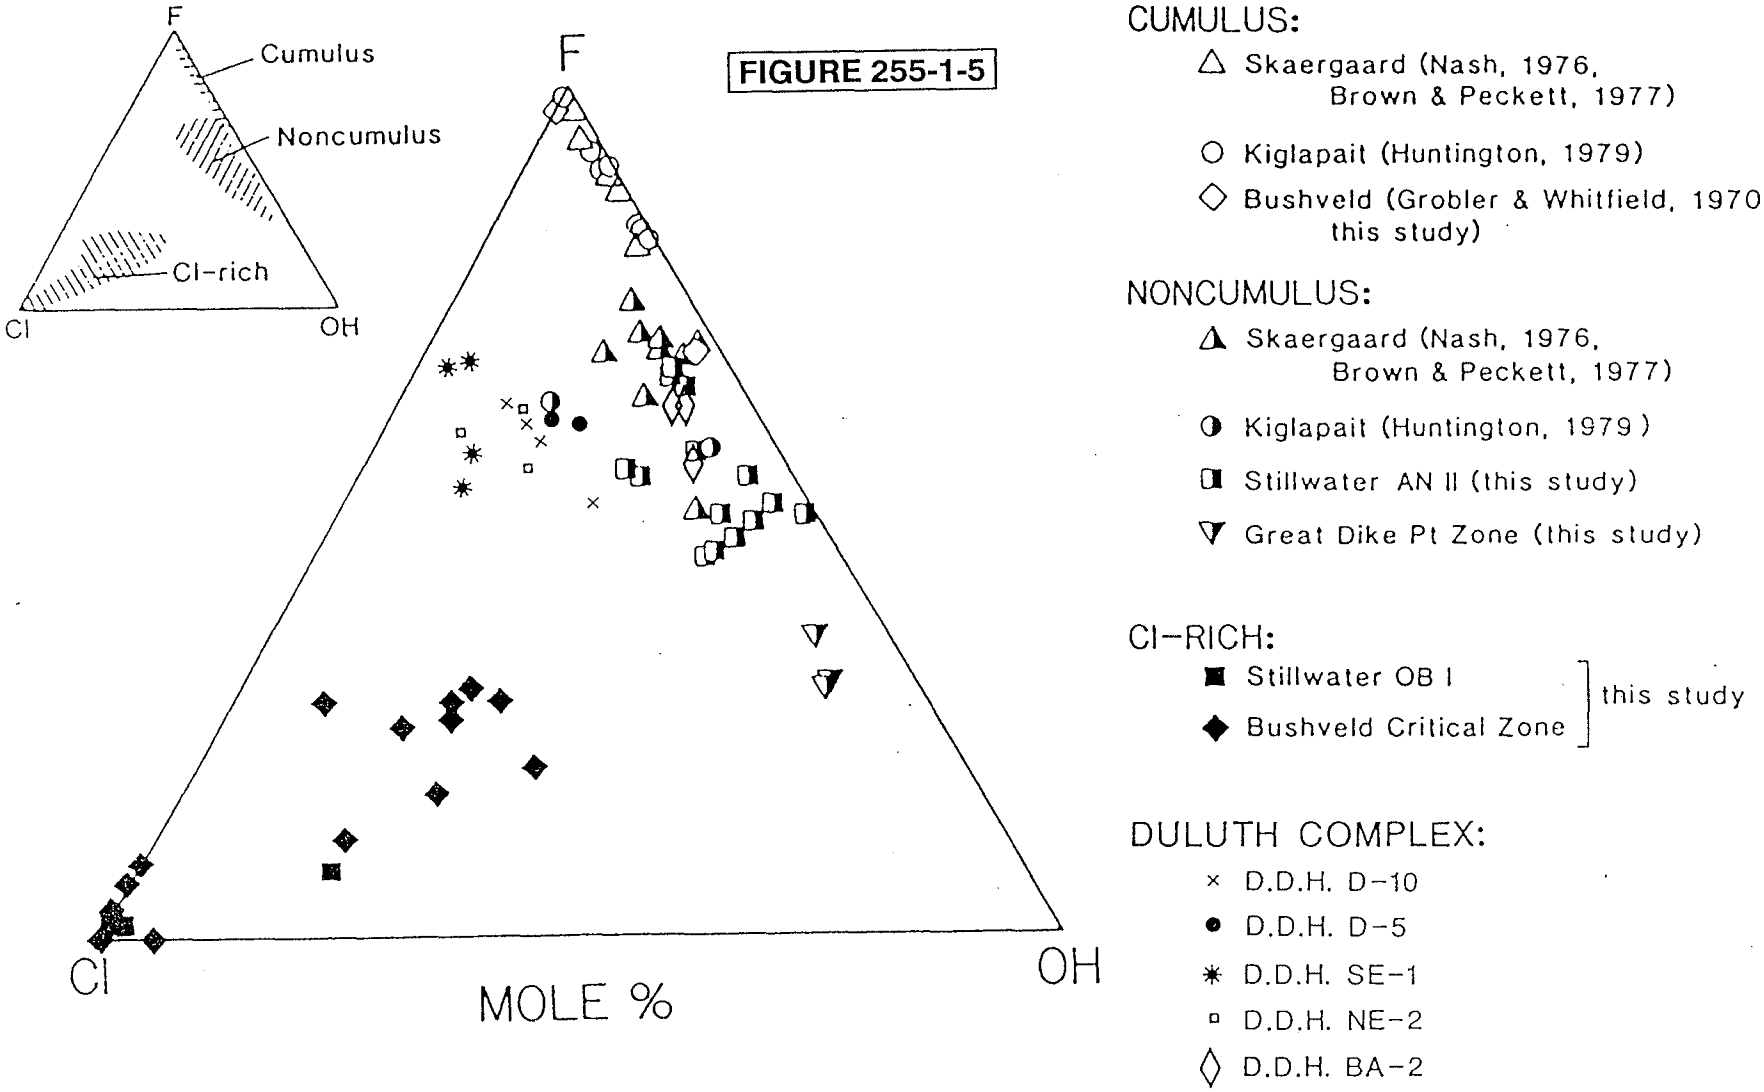
NOTES:

20304-1	100 x 140 um, fresh in plag
20304-2a	300 x 600 um, fresh core
20304-2b	300 x 600 um, fresh rim
20304-3	280 x 800 um, fresh lens-shaped gr in sulf
20303-1	1.2 mm, fresh rim
20303-2	1.2 mm, fresh core
13458-1	30 x 70 um, fresh
13458-2	40 x 40 um, fresh
13458-3	40 x 80 um, fresh but pitted
13458-4	50 x 80 um, fresh
13249-1	120 x 60 um, fresh but pitted surface
13249-2	130 x 130 um, fresh
13249-3	130 x 130 um, fresh
20305-1	big fresh grain
20305-2	150 x 500 um, fresh
20305-3	big grain, fresh

TABLE 255-1-10

APATITE COMPOSITIONS OF MAFIC LAYERED INTRUSIONS

FIGURE 255-1-5



A comparison of the compositions of cumulus,noncumulus, and Cl-rich ore zone apatites from the Stillwater, Bushveld and Duluth Complexes, the Kiglapait and Skaergaard Intrusions and the Great Dyke. After Boudreau and others (1986).

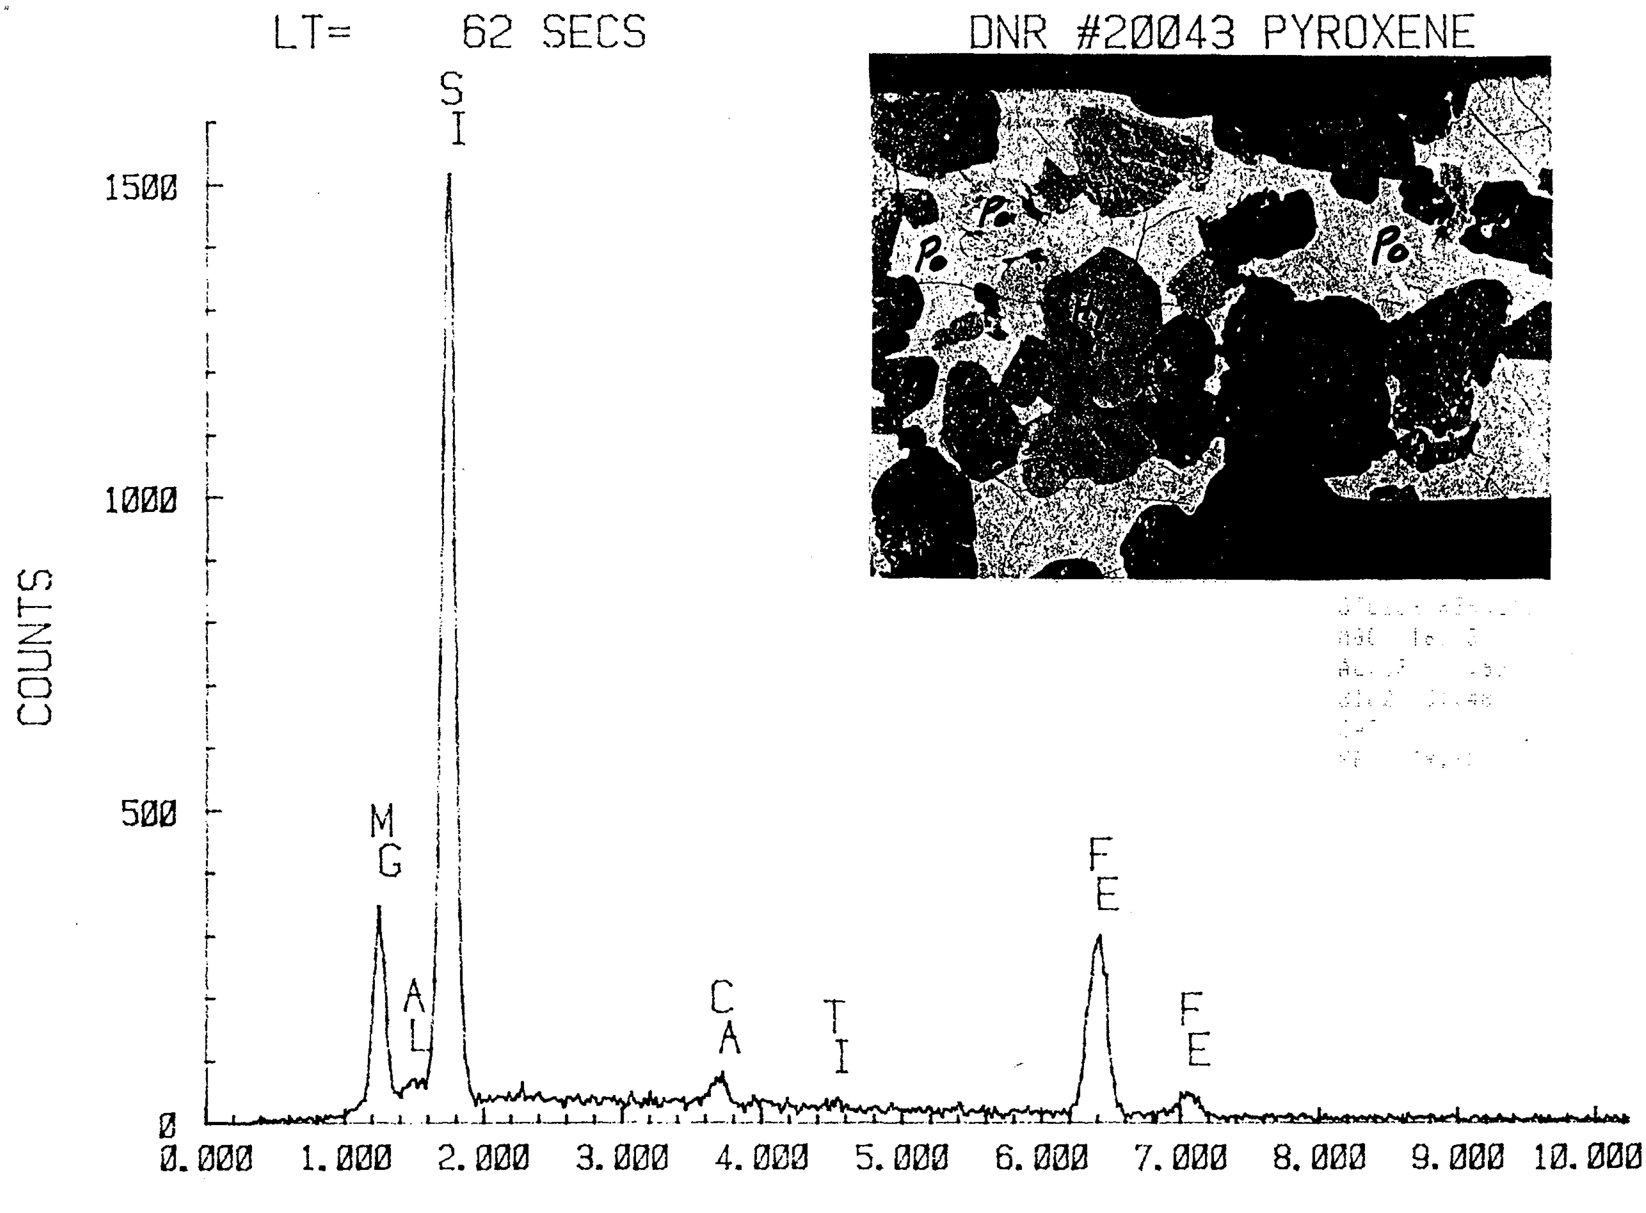


FIGURE 255-1-6

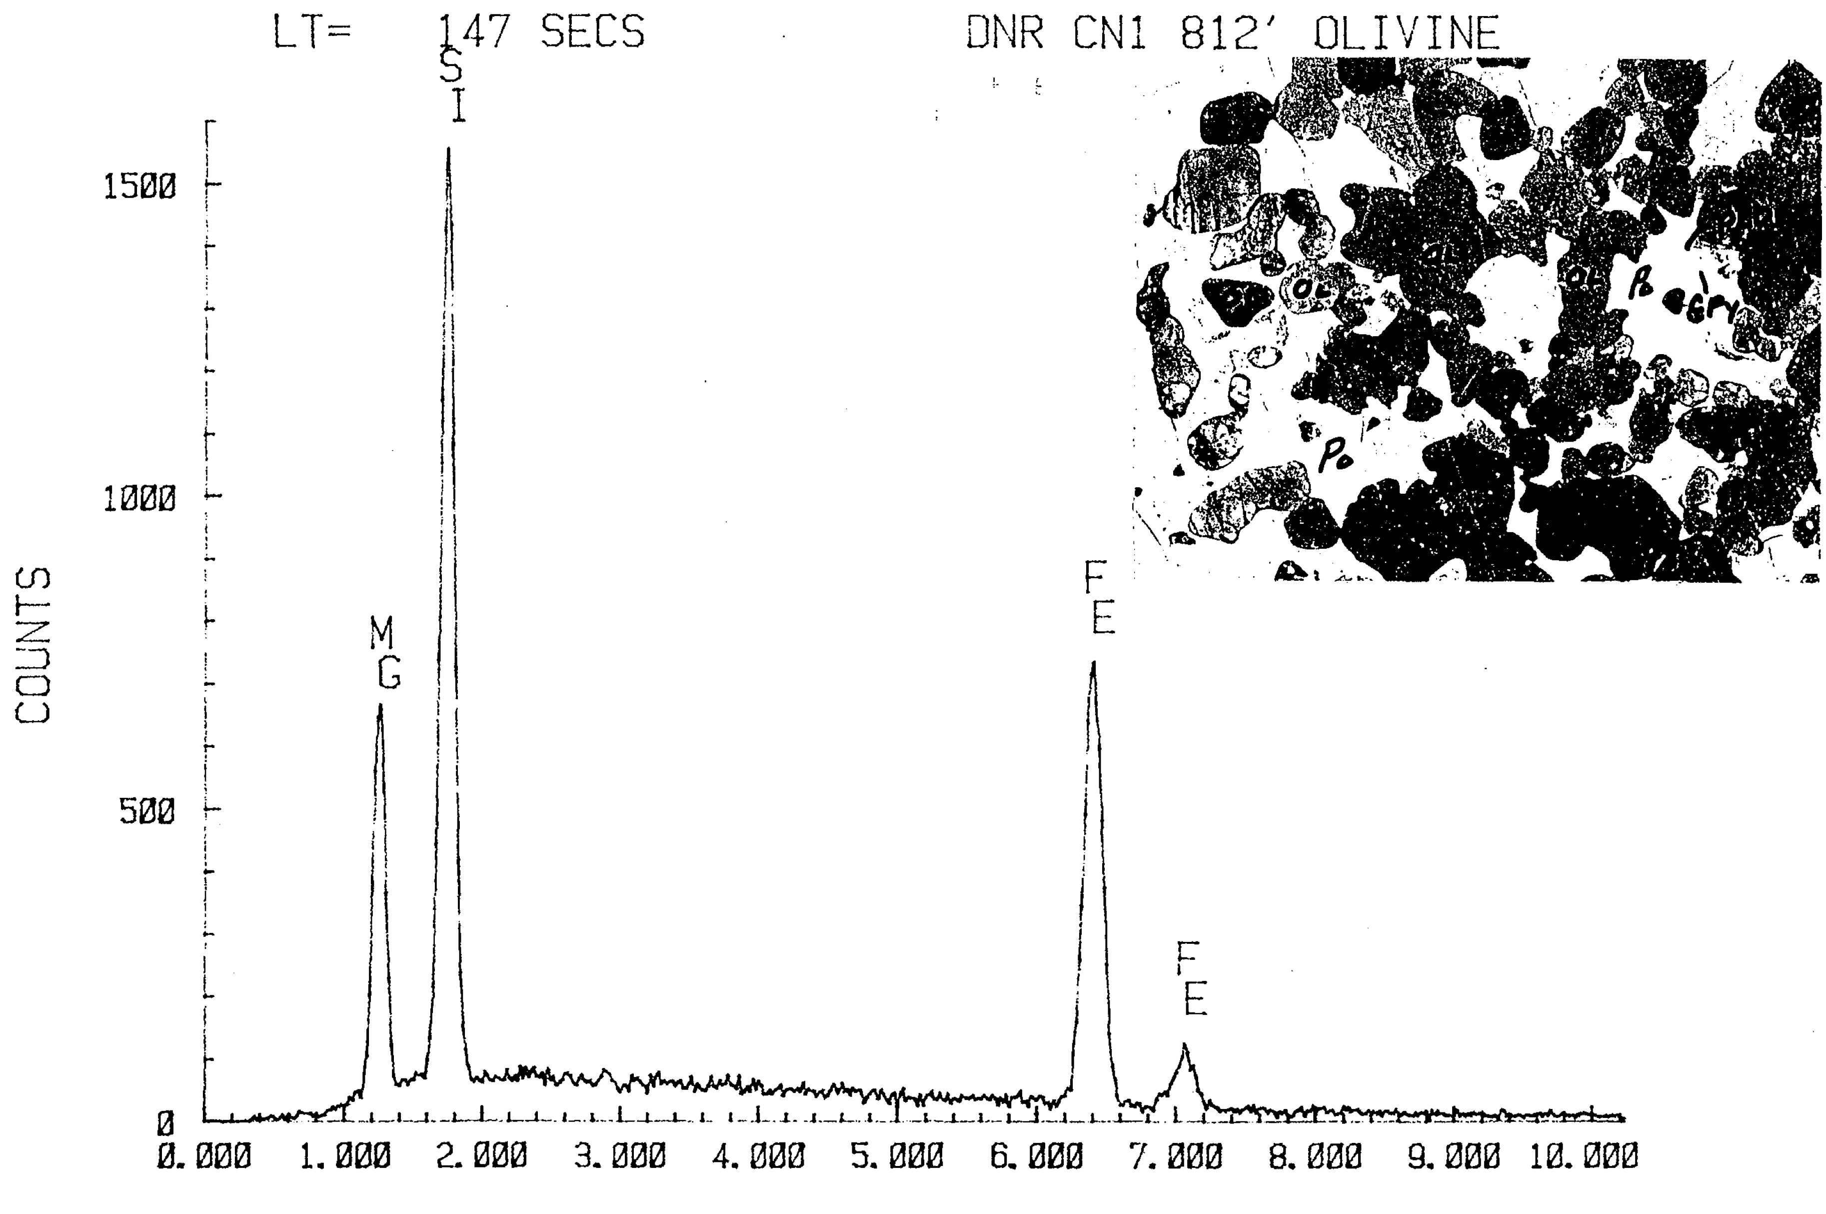

FIGURE 255-1-7

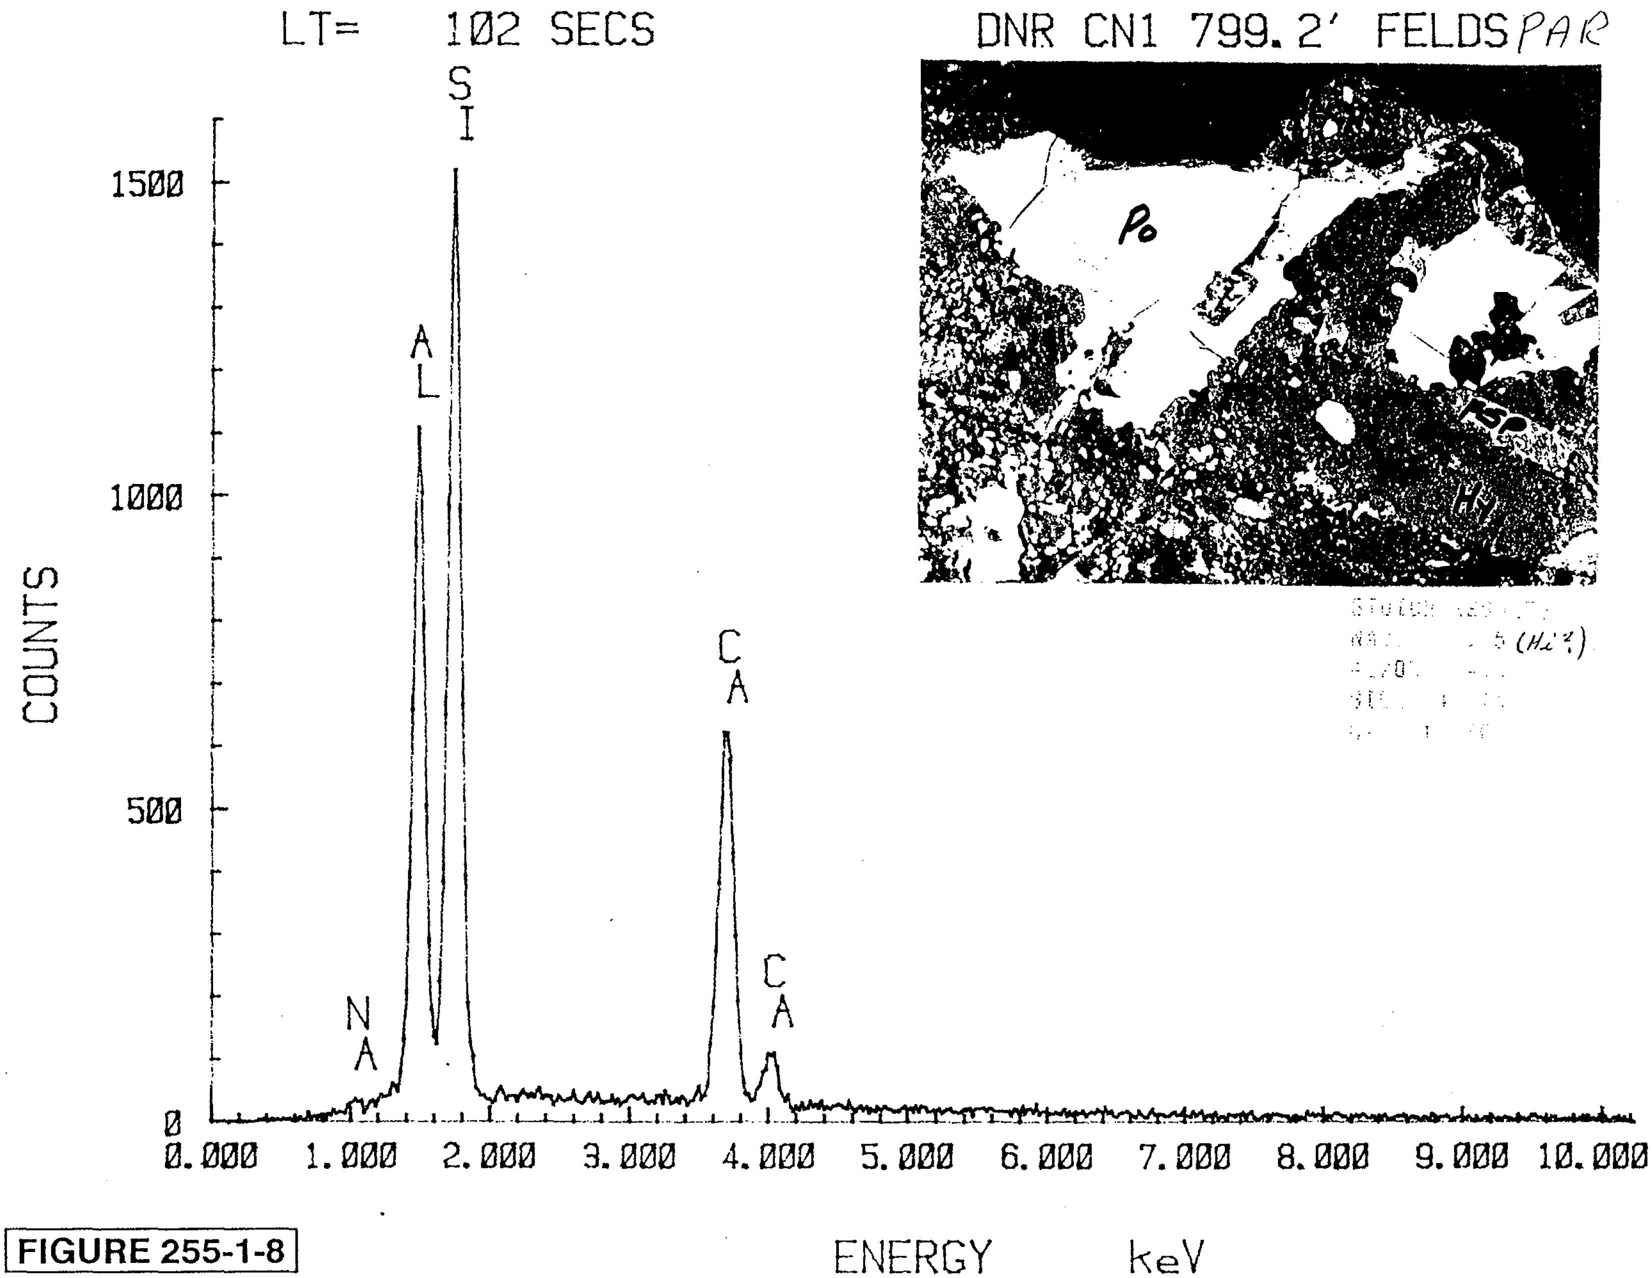

FIGURE 255-1-8

turned out to be zircons intergrown with chlorite.

Sample CL 20314 (DDH BA-3, 3510') *"What mica species" are these?* Based on the SEM/EDS spectra, the Mg:Fe ratio of .6:1 indicates that the mica was biotite, not phlogopite.

Sample CL 20315 (DDH BA-3, 3546') *Are these "tourmaline intergrown with zircon"?* By XRD, the black mineral was tourmaline (var dravite), and by EDS, the brown mineral was sphene.

Cannon Microprobe/SEM Work

Bart Cannon, of Cannon Microprobe located in Seattle, Washington took a number of SEM images on samples with the following results:

Sample CSL 18590 (DDH BA-1, 2690') imaged a grain of sperrylite.

Sample CSL 17711 (DDH DU-9, 2591') imaged a number of grains of tetraferroplatinum and isoferroplatinum grains. A quick analysis of a chromite from this chip showed it to be aluminous (with little magnesium). Most of the chromites showed 2 phases to be present (a lighter Al phase and a darker more Mg rich phase).

Pt and Pd trace element analysis of the pentlandite was performed on a few samples, but no results were above the detection limit of 0.1 wt%.

Sample CSL 20316 (DDH BI-144, 675-685') contained a mineral with Pd, Bi, and Sb in equal atomic proportions, with only 2% Te present. This is not a previously described species.

Chlorine Brines

The rusty-red fluid drops on drill core are related to a iron-OH-chlorine crystalline phase observed in partly serpentinizing olivine (Dahlberg et. al, 1988).

CONCLUSIONS

The highest density of elevated Pt + Pd + Au values and the largest volume of rocks with these values occur to the east and southeast of the Minnamax area and the geology is characterized by the relative abundance of anorthositic rocks.

Elevated values occur all along the basal zone; however, Du-15 and Du-9 still stand out as being relatively unique.

Project 265

SOUDAN MINE SAMPLING PROJECT

ABSTRACT

This project analyzed 251 samples from 25 drill holes from the Soudan Mine, currently a part of the Soudan Mine State Park. Drill holes resulted from development drilling when this Algoman-type iron formation was actively mined by Oliver Iron Mining Company (now USX) from 1882 to 1962.

Gold mineralization of several hundred ppb's appears to be breccia related. Other samples contained anomalous Ba and F.

Samples were analyzed for the following elements:

Au, Pt, Pd, Bi, Sb, As, B, Ba, S, Se, Te, Ag, Cu, Ni, Mo, W, Sn, F, Ga, Sc, Y, La, Ce, Zr, Nb, Ta, Cd, Zn, Pb, Cr, Co, V, TiO2, MgO, Fe2O3, MnO, SiO2, Al2O3, P2O5, Li, Na2O, K2O, Rb, Sr, CaO, and Be.

INTRODUCTION

The Soudan Mine was the first iron ore mine in the State of Minnesota. It operated, nearly continuously, from its discovery in 1882 to its closing in 1962 (Sims and Morey, 1966), which occurred due to rising production costs and a decreasing demand for high grade lump iron ore.

During operations, development drilling was a necessity and over 830 boxes or bags of core still exist from a total of at least 361 drill holes. Records indicate that more than 170 others have been drilled for which no core remains. No other area of Minnesota greenstone belt rocks has so much 3 dimensional information available.

It is highly unlikely that Soudan Mine iron ore will ever be needed, but the information stored in its drill core may be of benefit in the search for gold and other metals within the Vermilion Greenstone Belt. This is one of the more active areas of private company mineral exploration in Minnesota.

SOUDAN MINE BACKGROUND

Location

The Soudan Mine (within portions of sections 27 and 28 of Township 62N, range 15W) is located in the town of Soudan on the eastern edge of Lake Vermilion, at the western end of the Vermilion Iron Range. Soudan lies 70 miles north of Duluth, Minnesota, and 62 miles northwest of the north shore of Lake Superior and is in St. Louis Co. From Tower-Soudan, the iron formation extends 37 miles eastward through Ely (Reid and Hustad, 1950) and southeastward for another 10 miles.

Exploration History and Soudan Mine Description

The first indications of massive hematite on the south shore of Lake Vermilion came as a result of a gold rush in the area during the 1860's (Klinger, 1960). Despite a number of reported gold (and other metals) occurrences (Martin, 1985), no gold deposits were ever discovered and mined.

Development started at the Soudan Mine in 1882, with the first iron ore shipped in 1884. It produced ore nearly continuously until 1962 when it closed (Sims and Morey, 1966). During its history, it yielded about 15.5 million long tons of iron ore (Sims, 1972a). The mining method used was horizontal cut-and-fill.

Several steeply dipping ore bodies were mined at Soudan. At least 12 shafts were sunk in the mine area (Klinger, 1960). Over 50 miles of workings had been emplaced and mining was well underway on the 27th level at a depth of 2,400 feet when the mine closed. Some development-exploration drilling was completed down to the projected 29th level.

Since 1965, Soudan Mine has been operated as a State Park, and it is one of the few places open to the public which offers underground tours. These tours take people down the inclined (78 degrees) No. 8 shaft to the 27th level, where they are transported by an electrically powered train to the workings of the Montana orebody in the northwestern part of the mine (Sims and Morey, 1966).

Several other iron mines opened and closed on the Vermilion Iron Range, with Tower-Soudan and Ely being the major centers of mining.

At present, mineral exploration (mostly for gold) is being conducted throughout the greenstone belt rocks of the Vermilion Iron Range.

Geology

The geology of the Soudan is well summarized by Sims, 1972 and the Vermilion district as a whole by Hudleston, Schultz-Ela, and Southwick (1988). The Soudan Mine occurs in the Archean Soudan Iron Formation (SIF) (Algoman type). This is part of the Vermilion District, which consists of deformed low grade metavolcanic and metasedimentary rocks and various intrusive rocks forming an elongate belt about 10-30 km. wide and more than 160 km. long. This volcano-sedimentary pile and the Giants Range batholith which bounds it on the south, are a continuation of the Wawa-Shebandowan subprovince of the Superior Province in Canada. The Vermilion district is bounded on the north by granitic and migmatitic rocks of the Vermilion granitic complex which is part of the Quetico gneiss belt.

The SIF occurs as the largest and most continuous of the typically thin, lensoidal iron formations found in the volcanics and sediments of the Vermilion district. The SIF is traceable for at least 16 miles and has an outcrop thickness (not true thickness) of as much as 3000', although multiple folding is probably responsible for most of this. The SIF occurs at a major volcanic transition from older mafic flows and pyroclastics to younger dacitic tuff and agglomerate.

The SIF, as described lithologically by Klinger (1960), is composed of predominantly ferruginous cherts, with lesser volcanics, intrusive rocks, and other facies of iron formations. Jaspilite, a banded (often finely) chert-hematite-martite-magnetite rock (often magnetic) containing about 30% iron, appears to be the predominant host rock for the orebodies. The orebodies occur as steeply plunging sinuous to lenticular bodies, the largest dimensions being described as 100 feet wide, 1000 feet long and with depths ranging up to 2,500 feet (Klinger, 1960). The orebodies are typically composed of massive bluish gray hematite, with small quantities of quartz, chlorite, apatite, and local pyrite, and copper minerals (Sims, 1972a, Klinger, 1960).

Inherited textures, such as banding and brecciation, offer evidence for replacement acting as the ore deposit formation process. The same hydrothermal fluids probably also formed the iron rich "blackrock" and red "paintrock" by attacking volcanic rocks along with the more easily replaced jaspilite.

Kendall (1938) noted the following:

1. Zircon was locally abundant in chlorite schist.

2. "Secondary (but not always) minerals" include sericite, chlorite, leucoxene, rutile, calcite, dolomite, zoisite, uralite, magnetite, actinolite, tremolite, epidote, quartz, hematite.

3. Pyrite occurred as well developed cubes and in massive form.

Eby and Berkey (1897) have described malachite, azurite, cuprite and native copper, and Klinger has described chalcopyrite, bornite, native copper (and probably chalcocite and cuprite) in the western section of the mine. These minerals occur mostly as fracture fillings and vug linings. Klinger notes that pyrite and chalcopyrite are usually found in the ore or in the iron formation adjacent to the ore, especially near the periphery of the ore bodies. In addition, he states that chalcopyrite is rarely found in the schists, and he also reports one instance where chalcopyrite cements an ore breccia. One fault passing through the mine is called the "copper fault" because of pieces of native copper taken from it, and several of these are on display at the Soudan Mine Park Visitor Center.

Another mineral identified by Klinger was kaolinite. This occurred along some fractures in ore as a constituent of vugs, and in secondary veinlets in iron formation near the ore.

Klinger states that in addition to calcite occurrences, dolomite, siderite, and possibly marcasite occur as rare, but large specimens in vugs.

Vugs containing well developed quartz crystals were found in the top and sides of ore bodies, and were used by the miners to determine when an orebody is ending (Hustad and Reid, 1950).

One feature that makes the Soudan Mine an ideal touring mine, is its dryness. Unlike the mines at the Ely end which were very wet, needed extensive timbering, and were subject to dangerous rock falls; the rock of the Soudan Mine appears to be relatively tight, well cemented, and not subject to failures.

METHODOLOGY OF SAMPLING

All drill logs, analytical results, and other data were placed in open file for public examination on a monthly basis as they were received. This included the duplicate and standard sample analyses.

Pre-Sampling Work

All drill core sampled in this project is currently stored at the Soudan Mine State Park. Initially, there was no information available on what drill core was, or wasn't, available, so an inventory was made of all boxes and bags found containing drill core, and this list is Appendix A.

Note: All written material and mine maps are open filed at the DNR Minerals office in Hibbing, MN.

Each entry in Appendix A represents one box or bag of drill core found at the site. Most of the core is stored in wooden boxes (of several physical sizes), and a few drill holes are stored in cardboard boxes. Most drill holes (especially those in wooden boxes) have been skeletonized, and only 1/5 to 1/3 of the original number of boxes (variable with each drill hole) remains. The original number of drill hole boxes, and/or the number of final cutdown boxes can sometimes be found, as they are often indicated on those drill logs that still exist.

Based on lithologic logs, drill recovery was variable, and this may account for some of the missing core intervals in the boxes.

The information shown in Appendix A is a list (not necessarily complete) of what has been found to date.

Initially, most information came from the outside of the core boxes. Wooden boxes were apparently often reused for more than one drill hole as core became skeletonized, and this led to superimposed writing obscuring some of the information originally recorded on the boxes.

Therefore, the actual information found on the outside of the boxes was quite variable. Almost all boxes had either the mine drill hole number or the U.S. Steel (now U.S.X. Corporation) unique drill hole number, and most had the box number or the footage interval. Many also had an indication of the remaining number of cutdown boxes (e.g. "Box 2 of 3", and some boxes have the mine level recorded.

For some drill holes, more boxes exist than what the logs indicated, which may infer that some cutdown material was saved, or that there were test holes, redrills or extensions associated with that particular drill hole. Opening every box and examining the contained footage intervals might solve some of these discrepancies.

Core from some of the short drill holes lacking identifying numbers may be redrills, extensions of previous drill holes, or test holes. Their locations may yet be gleaned by comparing core lithologies and footages, with mine maps, and drawings. At least one drill hole, had 2 boxes labelled "Box 1" with 1 mine drill hole number, but 2 different U.S.S. unique numbers shown.

Some information is missing, and other information may be contradictory. Further work and investigation is necessary to fill in these gaps.

Core box information was complemented by written information, which is indicated in the DDH Information Inventory (Appendix b). Data was gathered from written information (maps, logs, etc.) in a variety of forms. Appendix B lists those documents that were found during the course of the work. Each entry is a separate drill hole number, followed by the type, "name" and location of the information source(s) which reference that particular drill hole. Other types of information included graphic logs, descriptive logs, level plan maps, cross-sections, etc. This data is on file at the Soudan Mine State Park, U.S.X. Corporation, Minnesota DNR Minerals Division, and Ironworld U.S.A. The Minerals division of the DNR in Hibbing currently has most of these materials on open file.

An unplanned part of this project included the assembling of core shelves and the removal of wooden boxes off of a wet floor in the building at the mine where the core is stored. Many boxes were originally stored on end, and the core inside of them became scrambled as the ends of the boxes rotted out. Boxes were rebuilt when it was absolutely necessary.

The following is an explanation for the columns found in "Soudan Mine Drill Core Inventory" (Appendix A).

MINEDDH = Mine drill hole number used at the Soudan Mine.

BOX# = Number of particular box of drill core for a given hole.

TOTBOXES = Total number of core boxes for a particular drill hole.

BXTPFT = Drill footage at top of box.

BXBTFT = Drill footage at bottom of box.

BXCODE = Codes are separated by a decimal point if more than one applies.

- 1 = Complete core.
- 2 = Skeletonized.
- 3 = Scrambled.
- 4 = Core stored in bags (scrambled).
- 5 = Box labelled "EXT" for extension of previously drilled hole.
- 6 = Box labelled "Test Hole" (associated? with drill hole of same number).
- 7 = Core in cardboard boxes, not wooden boxes.
- 8 = Core stacked on floor next to shelf "X".
- 9 = Core in back room on ground floor.

LEVEL = Mine Level where drill hole was collared. "0" Level is ground surface.

NSGRID = North or South coordinate of drill hole on Mine grid.

NorS = Designates whether above coordinate is North or South.

EWGRID = East or West coordinate of drill hole on Mine Grid.

EorW = Designates whether above coordinate is East or West.

AZIM = Azimuth direction (relative to Mine Grid North) that the hole was drilled.

ANGLE = Vertical angle at which the hole was drilled (0 = horizontal, -90 = vertically down). Some logs did not show a positive or negative sign, and the angles are shown as being positive.

SHELF = Designation of shelf unit where core is stored.

TDFT = Total depth or footage of drill hole.

USS# = Unique number given to all U.S. Steel drill holes.

ELEVATION = Drill hole collar elevation relative to the elevation of the surface of Lake Superior.

The mine grid to which the above coordinates and azimuths refer has "North" oriented approximately 13 degrees west of "true" North. The grid "zero" is located approximately 744 feet south and 1443 feet east of the western quarter section corner of Section 27, Township 62 N, Range 15 W. This information was scaled off of maps, and is subject to the accuracy limitations. Original survey notes, if they exist, would be necessary for work requiring any greater precision.

Sampling Procedures

The core from each drill hole was laid out in its entirety whenever possible. A general examination was made, and then temporary markers were used to indicate lithologic breaks of distinct units and to mark areas of interest, including those to be sampled.

Core samples were sawed and bagged in accordance with the Department of Natural Resources core sampling procedures. A sample card containing the sampling information has been left within each interval. Some intervals are contained in more than one box, and consequently may appear to lack a sampling card if the wrong box is examined.

Sampling Criteria

The following criteria were used when selecting samples for analysis:

1. presence of sulfide or sulfosalt minerals;

2. presence of veining, especially with quartz, carbonate, sulfides;

3. chemical sediments such as cherts (especially with disseminated sulfides), iron formation (especially when sulfidized), carbonates (especially iron dolomites), tourmalinites, sulfides and graphitic rocks (?);

4. fractured-faulted intervals and adjacent rocks;

5. brittle-ductile deformation transitions;

6. lithologic contacts or transitions, including intrusive contacts;

7. oxidation-reduction, or other apparent chemical or process transitions;

8. unknown, dubious or unusual mineralogy or rock types.

Since Archean rocks often exhibit at least one of the above features, the overall philosophy was one of attempting to sample those intervals exhibiting the greatest variety of geologic processes.

Because of time and other constraints, certain procedures were followed with regard to sampling, and drill holes were preferentially sampled for the following reasons:

1. Available information indicated a number of the criteria cited above, or other intriguing features.

2. Available maps indicated that certain holes should intersect the "copper" or other faults.

3. Wide spatial placement, to get spatial information on variations in rock chemistry.

4. To develop chemical information on as wide a variety of lithologies and processes as possible.

5. To sample drill holes which had not been skeletonized.

During sample compositing, every attempt was made to keep the major lithotype of the subsamples the same.

A listing of the drill holes sampled is given in Table 265-1

SAMPLE PREPARATION AND ANALYSIS

Sample Preparation

Technical Service Laboratories, Ltd. (TSL) of Mississauga, Ontario was awarded the contract for sample preparation and the analytical work.

Samples were crushed to 1/4 inch in a jaw crusher and further reduced to 1/10 inch in a cone crusher. Each sample was then split and a 1/2 pound portion was pulverized to -150 mesh in a shatter box.

Some analytical samples were actually composites of subsamples. This involved taking equal weights of pulps from each of the subsamples, combining, and thoroughly mixing them before analysis. The majority of pulps, however, were not mixed (i.e., identities kept separate) and were reserved for separate analysis in the event interesting results came back from the analysis of the corresponding composite sample.

Analytical Work

Analytical results, including the duplicate and standard sample analyses, are presented in Appendix D.

Table 265-2 describes the analytical package used for greenstone - granite terrane rocks. The following abbreviations are used in this table:

% = percent (parts per hundred)

PPM = parts per million

PPB = parts per billion

FA = fire assay

ICP = inductively coupled plasma emission spectrometry

AA = atomic absorption

SP ION EL = specific ion electrode

WR = whole rock (inductively coupled argon plasma emission spectrometry)

INAA = instrumental neutron activation analysis

This table indicates the detection limits, the sample weight used, the analytical method, and the overlimit values for the elements (and some oxides) analyzed for. "Overlimit value" refers to the highest analytical value for which quality results can be produced for a given analytical method and element.

Other procedures involved with whole rock (WR) analyses include the following:

Fusion

Each gram sample was fused with a flux mixture of lithium carbonate and boric acid. Each fusion was carried out in a graphite crucible using a proprietary procedure.

Sample Dissolution

The molten sample and flux mixture were poured directly into a nitric acid solution contained in a plastic bottle. The molten slag shatters on impact and as a result, dissolves quite readily. Each bottle was then placed on a shaker for 4 hours to insure complete dissolution.

Table 265-2. ANALYTICAL PACKAGE FOR GREENSTONE-GRANITE TERRANE ROCKS, SOILS, AND OTHER GEOLOGIC MATERIALS.

ELEMENT	DETECTION LIMIT	SAMPLE WEIGHT grams	ANALYTICAL METHOD	OVERLIMIT VALUE

Internal Standard

After dissolution, each sample solution was diluted with water containing an internal standard. All dilutions used in this procedure were made to a constant or recorded weight. The samples were mixed and a portion filtered prior to analysis on the ICAP.

Standardization

An individual standardization by TSL is carried out by using five international standard samples. These samples have been obtained from the Canadian Certified Reference Material Project, United States Geological Survey, National Bureau of Standards (USA), Centre De Recherches Petrographics Et Geochmiques (France) and the National Institute for Metallurgy (South Africa). Standard samples are treated in the same manner as are actual assay samples. In the event that a sample is outside the range of the standards used (e.g., a limestone sample with silicate rock samples), it is rerun on the ICAP with the appropriate solution standards. Solution standards mean that samples with extremes of one element can be accommodated by the addition of that element in solution to appropriate standards. TSL has a standard group of approximately 35 standards that can be used as a routine. Standardization for the secondary elements (Zr, Sr, Ba, Sc, Y) is carried out in much the same manner in that known reference materials are used to control the analysis.

For ICP or AA work, a multi acid digestion was used. For each sample, 1.0 gram of pulp was treated with a combination of HF, HC104, HNO3 and HCl. Samples were digested, taken to HC104 fumes, diluted and analyzed by ICP or AA as required.

Instrumental Neutron Activation Analysis (INAA) was performed by Activation Laboratories, Ltd. Activation Laboratories, Ltd. is a joint venture company owned by Technical Service Laboratories and Dr. Eric Hoffman.

DUPLICATE SAMPLES

Several "known" samples were run for this project to check on the quality of the gold determinations from TSL. While initial results were disappointing, further work indicated the erratic results were possibly due to an irregular distribution within the sample (?). Some platinum group element work also produced inconsistent results, however, contamination during sample preparation may have been responsible.

Two pulps (sample #'s 20843 and 20844) were sent in with the Project 265 samples. They were made by diluting CANMET standard GTS-1 (346 ppb) with previously assayed barren pulp to hypothetical values of 50 and 200 ppb, respectively. They were assayed by Bondar Clegg, North Vancouver B.C., with results of 45 and 220 ppb, respectively (see Sellner, et al., 1985). Because the TSL results were 3 and 38 ppb, respectively, additional samples of these pulps and undiluted CANMET GTS-1 were requested to be analyzed. These values are listed below in TABLE 265-3. Note that the 150 ppb "spike" and "blank" values (used to calibrate ICP unit) are also given.

TABLE 265-3. TSL ANALYSIS OF GOLD STANDARDS FROM PULPS

Pulp Sample #	Given Standard Au Value	TSL Analysis Sample #'s	TSL Analysis Au Values
	blank		less than 1 ppb
20843	50 ppb standard	20846	32, 36 ppb
20844	200 ppb standard	20847	118, 121 ppb
	346 ppb (GTS-1 standard)	20848	219, 217 ppb
	150 ppb spike		138, 146 ppb

TSL (at their expense) also analyzed the 5 samples having the highest Au values (for the Project 265 sample group) using instrumental neutron activation analysis (INAA). These results are shown in TABLE 265-4.

TABLE 265-4 TSL FA-ICP AND INAA COMPARATIVE ANALYSES

Previous Sample No.	New FA-ICP Result	INAA Result
20786	197 ppb	180 ppb
19675	158 ppb	330 ppb
19674	113 ppb	55 ppb
19673	102 ppb	192 ppb
20662	232 ppb	207 ppb

We have also reanalyzed at Bondar-Clegg (BC), Inc. of North Vancouver, British Columbia separate samples of core from the most anomalous samples reported by TSL. BC used a fire assay with an atomic absorption spectrometry finish. After the results were (initially) received, Bondar-Clegg telephoned saying they had misread the instructions. The results they had sent were from 10 gram rather than 30 gram samples, so they redid the analyses with 30 gram samples. The results are printed in Table 265-5 including the platinum and palladium values:

The evidence is pretty strong for an irregular nugget effect due to gold grain size.

The B.C. results also indicate some discrepancy with the TSL results for the highest platinum and palladium samples. If contamination is involved, other elements (Cu, Ni) did not appear to be affected. The reason for the discrepancy is not clear, but sending the TSL pulps to BC, and the BC pulps to TSL may help to resolve this question.

TABLE 265-5

* Erratic gold results noted by assayer = 2760, 1125, 253 ppb when 10 gram sample repeated.

** Erratic gold results noted by assayer = 258 ppb when 30 gram samples repeated.

DESCRIPTION AND DISCUSSION OF RESULTS

The analytical results for this project are given in Appendix D. In Appendix C, the sample list, the rock names are essentially those used in the mine literature; however, the author used "hematite schist" in place of "paintrock". Plots of sample numbers vs. sample values are found in Figures 265-1, 265-2, 265-3, and 265-4.

The highest gold (Au) values were found only on the order of several hundred ppb's, and based on their association with breccias, they are probably fault related. Relationships with other elements are weak at best. The same can be said for Pt and Pd, but the lithologic association with brecciated rocks appears less certain, except in samples 19650 and 19651. In general, there appears to be more Pt than Pd in the system.

The samples with the highest Pt and Pd values (950 and 335 ppb respectively) were also analyzed by Bondar Clegg. They did not confirm the TSL results (see section on "Duplicate Samples").

Other interesting numbers in the analytical data include values of 3044 ppm Ba, 2360 ppm F, 1400 ppm Rb, 1350 ppm Sr, and 120 ppm Li.

The sample number vs. sample value plots show some interesting things. The Fe_2O_3 and SiO_2 plots are quite antipathetic, which may indicate of a general chemical process of one replacing the other(?). The Li plot matches up to a surprising degree, with MgO, TiO_2, and V, contrary to what one might expect.

Another trend that one would expect to see and, indeed, does see is that between K_2O and Al_2O_3, which is probably sericite associated.

FIGURE 265-1

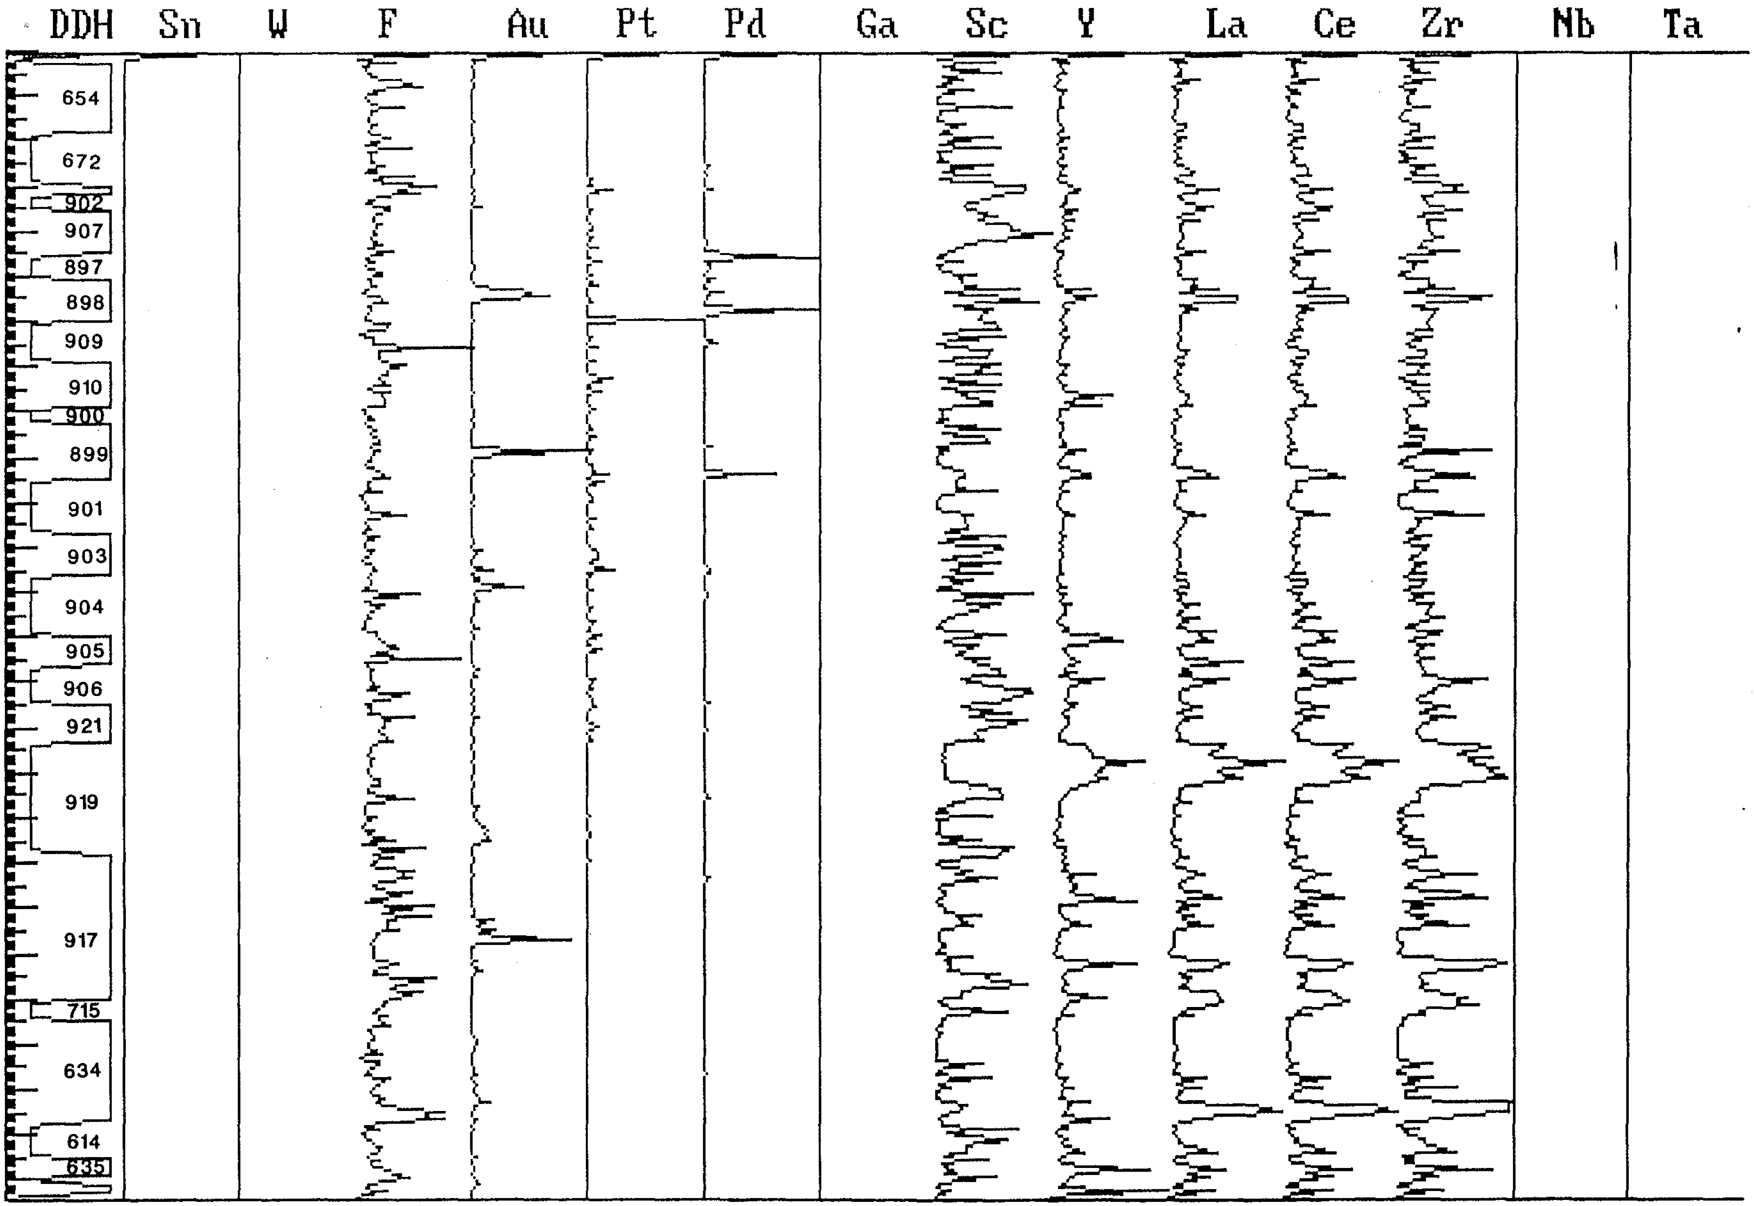

FIGURE 265-2: Sample Value vs. Sample # Plot for Soudan Mine Sample Analyses (Sn, W, F, Au, Pt, Pd, Ga, Sc, Y, La, Ce, Zr, Nb, Ta). Sample #'s are broken up by drill hole in the left column.

FIGURE 265-3

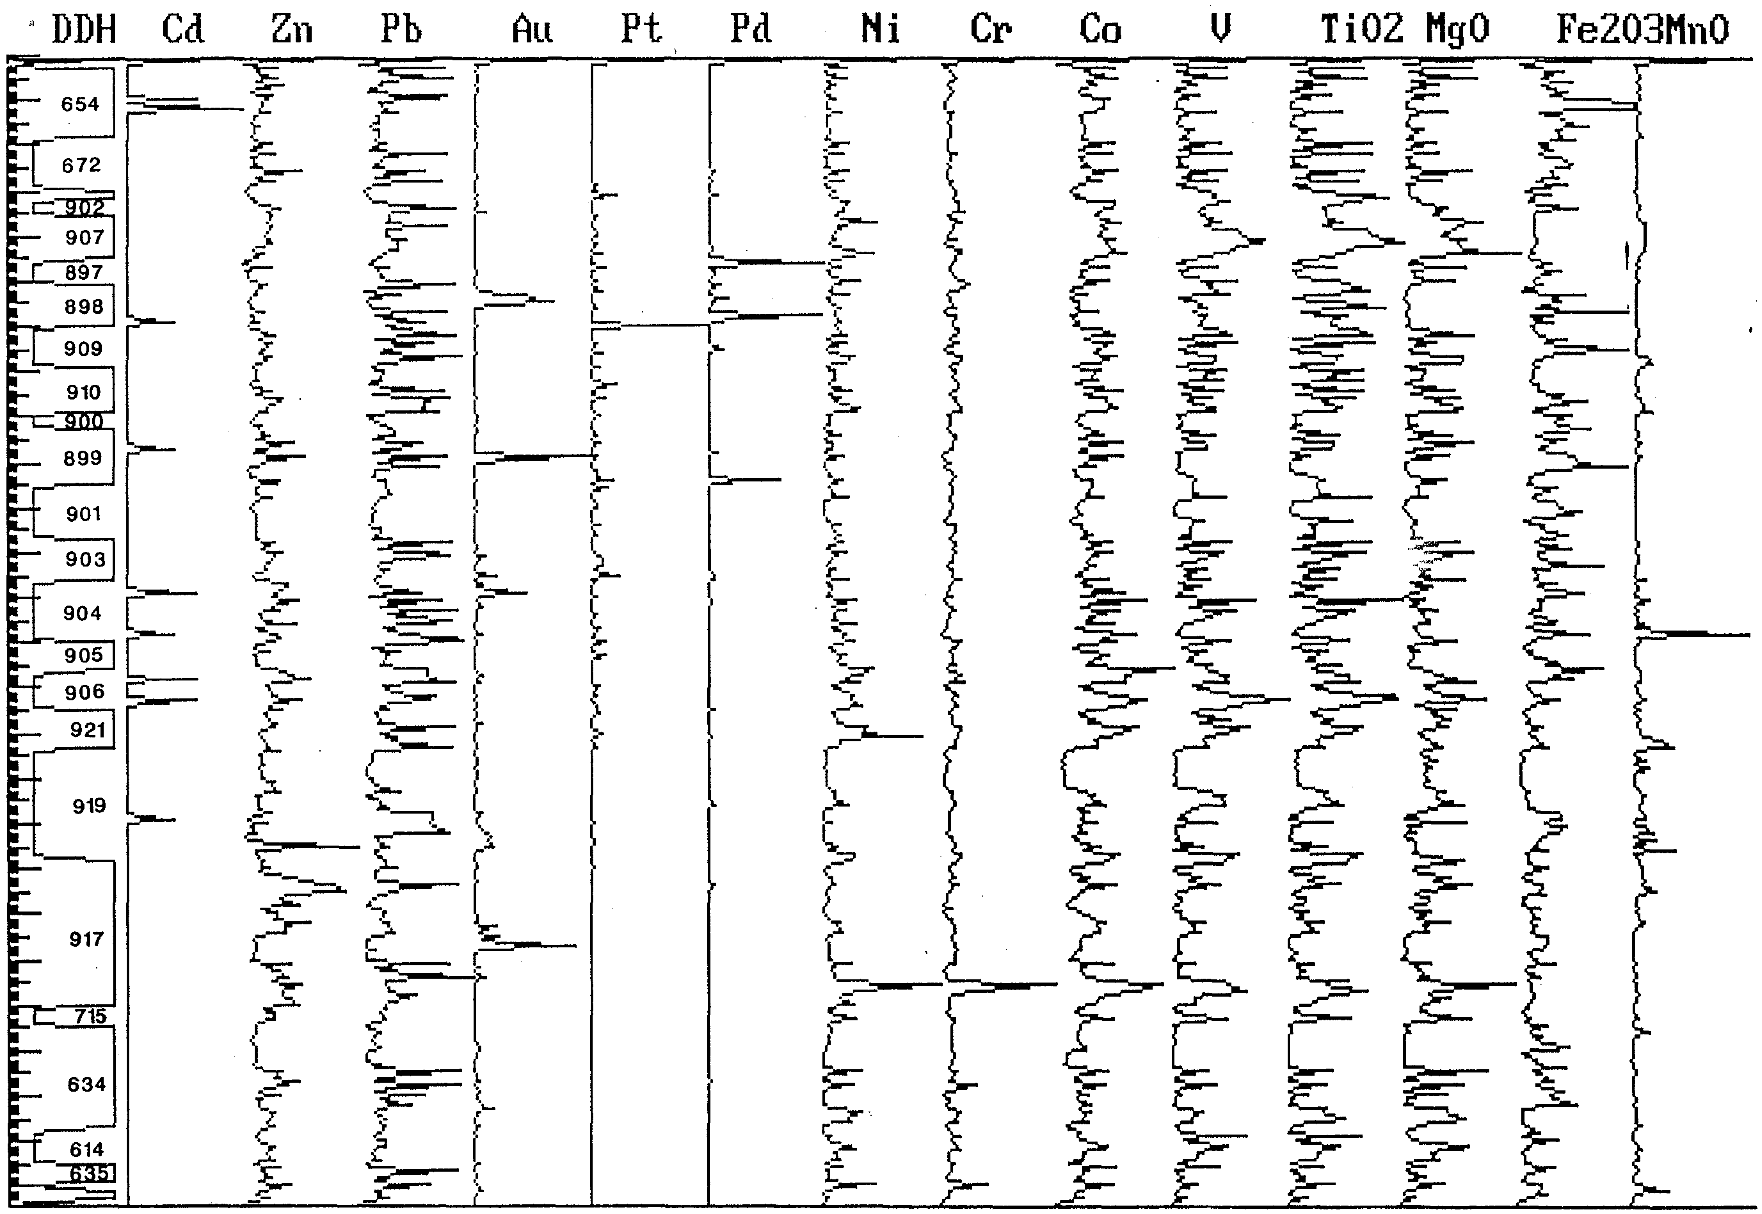

FIGURE 265-3: Sample Value vs. Sample # Plot for Soudan Mine Sample Analyses (Cd, Zn, Pb, Au, Pt, Pd, Ni, Cr, Co, V, TiO2, Mgo, Fe2O3, MnO). Sample #'s are broken up by drill hole in the left column.

FIGURE 265-4

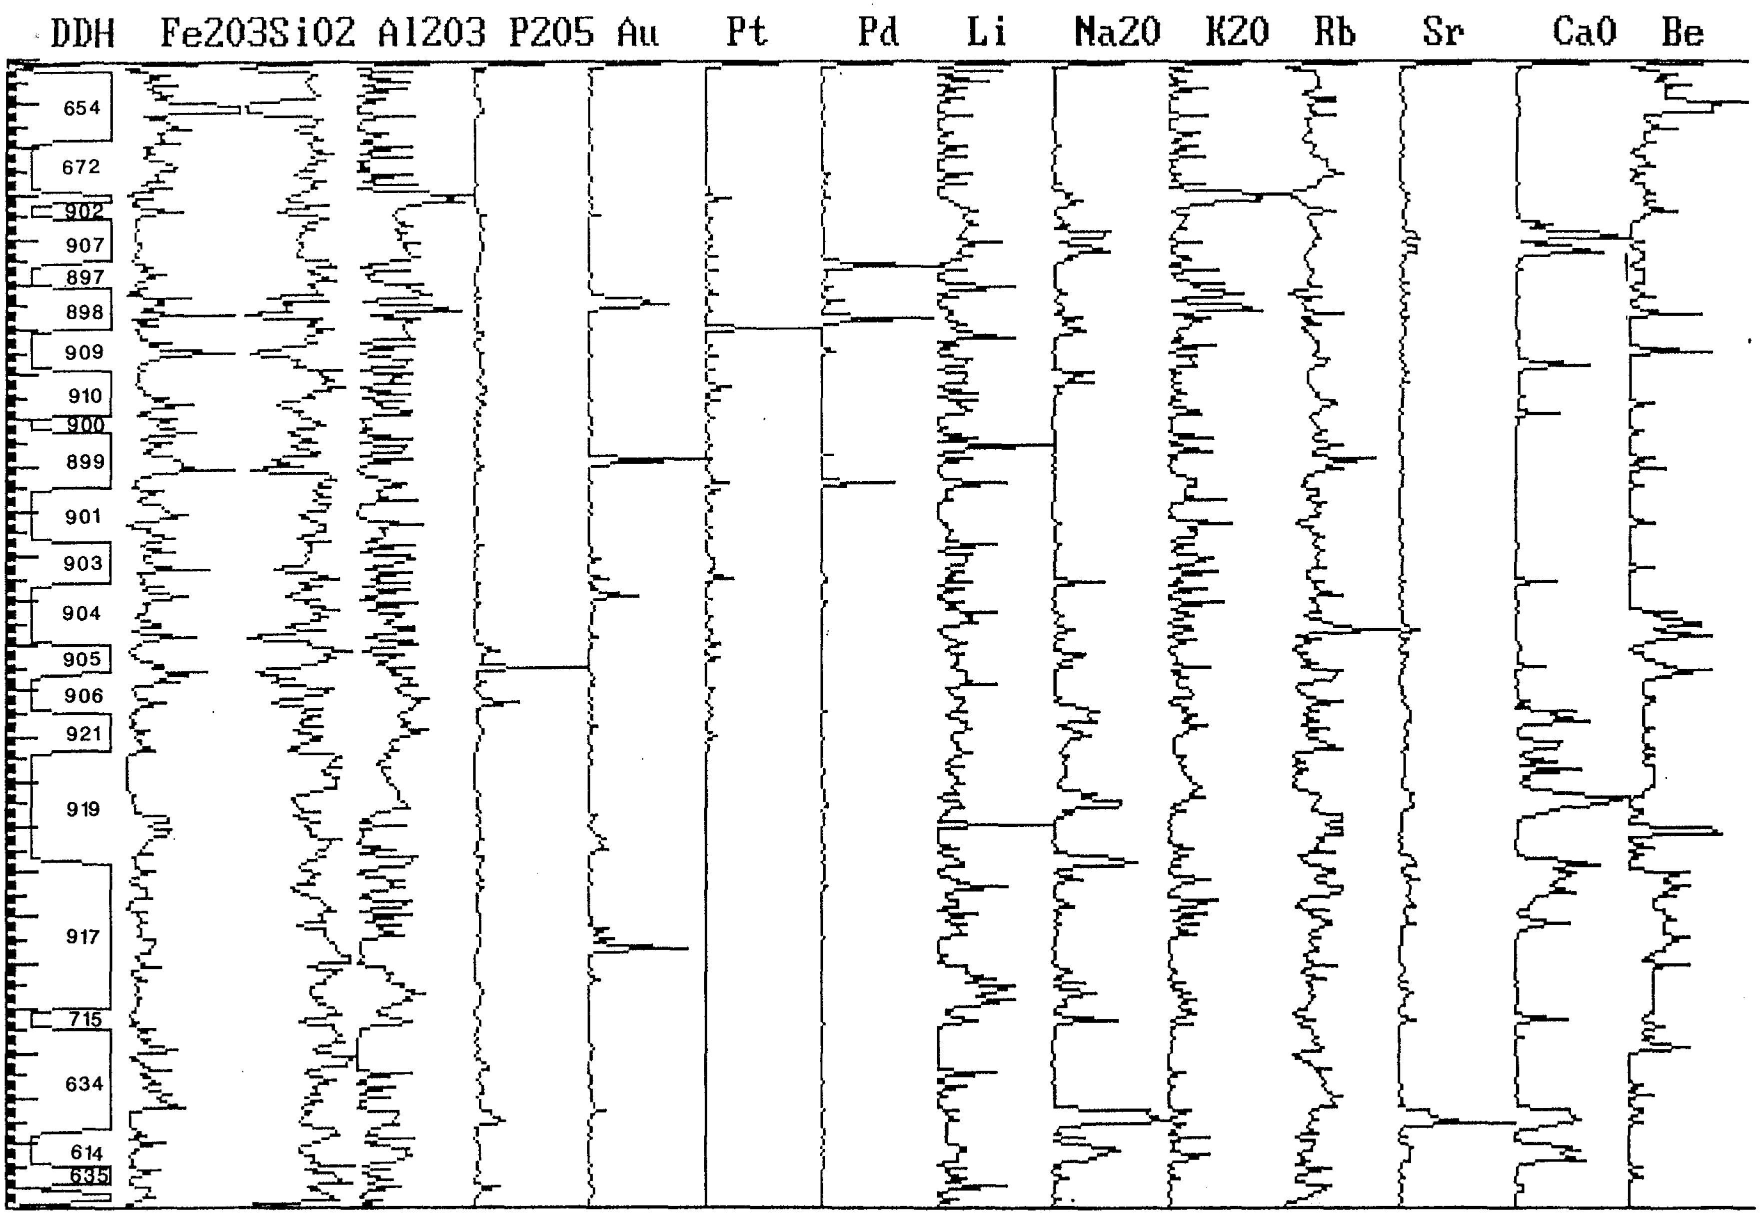

FIGURE 265-4: Sample Value vs. Sample # Plot for Soudan Mine Sample Analyses (Fe2O3, SiO2, Al2O3, P2O5, Au, Pt, Pd, Li, Na2O, K2O, Rb, Sr, CaO, Be). Sample #'s are broken up by drill hole in the left column.

CONCLUSIONS

1. The weak precious metal mineralization is fault related (solution conduit mechanism).

2. The geochemical processes appear to heavily involve both iron and silica, but reciprocally.

3. Some of the higher K2O values also appear to be breccia associated, indicating that sericitic alteration is fault controlled, which may indirectly link sericitization with precious metal mineralization.

RECOMMENDATIONS

More detailed sampling is needed since there is so much drill core located in a spatially small area. A Geographic Information System (GIS) study which spatially analyzes chemistry-stratigraphy would be most appropriate. The Soudan Mine is a unique place to do this. These systematics could then be applied to areas of similar rocks where there is less spatial control in three dimensions.

It is also recommended that the core be moved underground to less humid storage. The building in which the core is currently located has deteriorated badly.

No thesis work has been undertaken on the rocks at the Soudan Mine for a number of years. In view of the fact that the rocks have been extensively altered, and that there appears to be zoning with regard to the trace of pyrite in the orebodies, this mine would seem to be a good candidate for a thesis project.

Soudan Mine
Sampling Project

APPENDICES

APPENDIX A

The following is an explanation for the columns found in "Soudan Mine Drill Core Inventory" (Appendix A).

MINEDDH = Mine drill hole number used at the Soudan Mine.
BOX# = Number of particular box of drill core for a given hole.
TOTBOXES = Total number of core boxes for a particular drill hole.
BXTPFT = Drill footage at top of box.
BXBTFT = Drill footage at bottom of box.
BXCODE = Codes are separated by a decimal point if more than one applies.
- 1 = Complete core.
- 2 = Skeletonized.
- 3 = Scrambled.
- 4 = Core stored in bags (scrambled).
- 5 = Box labelled "EXT" for extension of previously drilled hole.
- 6 = Box labelled "Test Hole" (associated? with drill hole of same number).
- 7 = Core in cardboard boxes, not wooden boxes.
- 8 = Core stacked on floor next to shelf "X".
- 9 = Core in back room on ground floor.

LEVEL = Mine Level where drill hole was collared. "0" Level is ground surface.
NSGRID = North or South coordinate of drill hole on Mine Grid.
NorS = Designates whether above coordinate is North or South.
EWGRID = East or West coordinate of drill hole on Mine Grid.
EorW = Designates whether above coordinate is East or West.
AZIM = Azimuth direction (relative to Mine Grid North) that the hole was drilled.
ANGLE = Vertical angle at which the hole was drilled (0=horizontal, -90=vertically down). Some logs did not show a positive or negative sign, and the angles are shown as being positive.
SHELF = Designation of shelf unit where core is stored.
TDFT = Total depth or footage of drill hole.
USS# = Unique number given to all U.S. Steel drill holes.
ELEVATION = Drill hole collar elevation relative to the elevation of the surface of Lake Superior.

The mine grid to which the above coordinates and azimuths refer, has "North" that is oriented approximately 13 degrees west of "true" North. The grid "zero" is located approximately 744 feet south and 1443 feet east of the western quarter section corner of Section 27, Township 62 N, Range 15 W. This information was scaled off of maps, and is subject to the accuracy limitations that doing so implies. Original survey notes, if found, would be necessary for any work requiring any greater precision.

SAMPLE LIST

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
634(cont.)	20807		26-28		Jasper, minor magnetite pyrite.
	20808		32.5-40		Jasper with magnetite pyrite.
	20809		40-42		Jasper with magnetite.
	20810		45-47		Chert with hematitic streaks.
	20811		61-66		Breccia chert hematitic jasper with breccia with pyrite.
	20812		67½-74.5		Breccia chert hematitic jasper with pyrite.
	20813		80-82		Breccia hematitic, jasper, chert with pyrite.
	20814		82-95		Chlorite schist.
	20815		106-107		Chert jasper magnetite with pyrite.
	20816		124-127		Chert magnetite.
	20817		127-132		Chlorite schist with chert, pyrite.
	20818		132-145		
	20819		145-150.5		
		20819a		145-148	Chlorite sericite schist
		20819b		150-150.5	with pyrite.
	20820		148-158		
		20820a		148-150	Jasper chert magnetite
		20820b		150.5-158	with pyrite.
	20821		158-162		Magnetite jasper with pyrite.
	20822		162-164		Talc sericite siliceous schist with pyrite.
	20823		164-170		Sericite talc schist.
	20824		175-180		Sericite talc schist.
	20825		185-195		Talc sericite schist.
	20826		210-227		Chert silicified sericite schist with pyrite chlorite schist.
		20826a		210-215	
		20826b		215-220	
		20826c		220-225	
		20826d		225-227	

PROJECT 265
SAMPLE LIST

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
614	20827		0-15		
		20827a		0-5	Chert jasper.
		20827b		5-10	Chert jasper with breccia.
		20827c		10-15	Chert jasper with chlorite.
	20828		35-45		Siliceous sericite schist.
	20829		83-88		Chert jasper with breccia.
	20830		153-168		Chlorite schist with calcareous quartz veins.
	20831		168-172		Chlorite sericite schist.
	20832		172-178		Siliceous sericite schist.
	20833		203-208		Chlorite sericite schist.
635	20834		0-11		Breccia chert jasper.
	20835		11-15		Chlorite schist and jasper with pyrite, chalcopyrite.
	20836		35-40.5		Breccia chert jasper.
	20837		45-55		Chert breccia mylonite.
	20838		64-65½		Siliceous chert breccia with pyrite.
695	20839		85-90		Diorite intrusive.
751	20840		50-60		Chert with breccia.
	20841		60-74		Jasper with sulfides.
	20842		74-78		Chert with breccia, sulfides.
965*	20843		45-50		Siliceous sericite schist.
	20844		195-205		Siliceous sericite schist.

* This is an imaginary drill hole with the two samples being prepared pulps with previously analyzed Au values. See section on Duplicate Samples Results.

Project 266

ARCHEAN GREENSTONE SAMPLING PROJECT

ABSTRACT

This project analyzed 213 samples from 12 drill holes located in the granite-greenstone terrane of north central Minnesota (east central Beltrami County).

Gold values over 1 ppm were confirmed in DDH RL-25. Mineralization appears to be associated with Bi, Sb, As, Se, S, Ag, Cu, Mo, and Fe2O3. In DDH TIT-3, a small interval of calcareous "blackschist" alteration was observed, but the adjacent rock was only weakly mineralized.

Samples were analyzed for:

Au, Pt, Pd, Bi, Sb, As, B, Ba, S, Se, Te, Ag, Cu, Ni, Mo, W, Sn, F, Ga, Sc, Y, La, Ce, Zr, Nb, Ta, Cd ,Zn, Pb, Cr, Co, V, TiO2, MgO, Fe2O3, MnO, SiO2, Al2O3, P2O5, Li, Na2O, K2O, Rb, Sr, CaO, and Be.

INTRODUCTION

This ongoing project sampled Archean greenstone belt rock drill core which is maintained at the Department of Natural Resources Core Repository (Library) in Hibbing, MN. These drill holes are largely from private mineral exploration companies and were drilled in their course of exploration for predominantly base and precious metals. Due to finite resources, private companies usually do very limited sampling, and often for only those few commodities that are motivating their exploration at the time. The purpose of this project is to sample and analyze some of these drill cores for metals not initially looked for in geographical areas where mineral exploration has waned. Besides information on precious and base metals, whole rock and trace element data may prove useful in placing drill holes in a regional geological context. Moreover indications of alteration associated with mineralization may be found which is otherwise not detectable.

Another aspect of this project was to expand upon data available from previous drilling and sampling activity within selected areas.

STRUCTURE OF REPORT

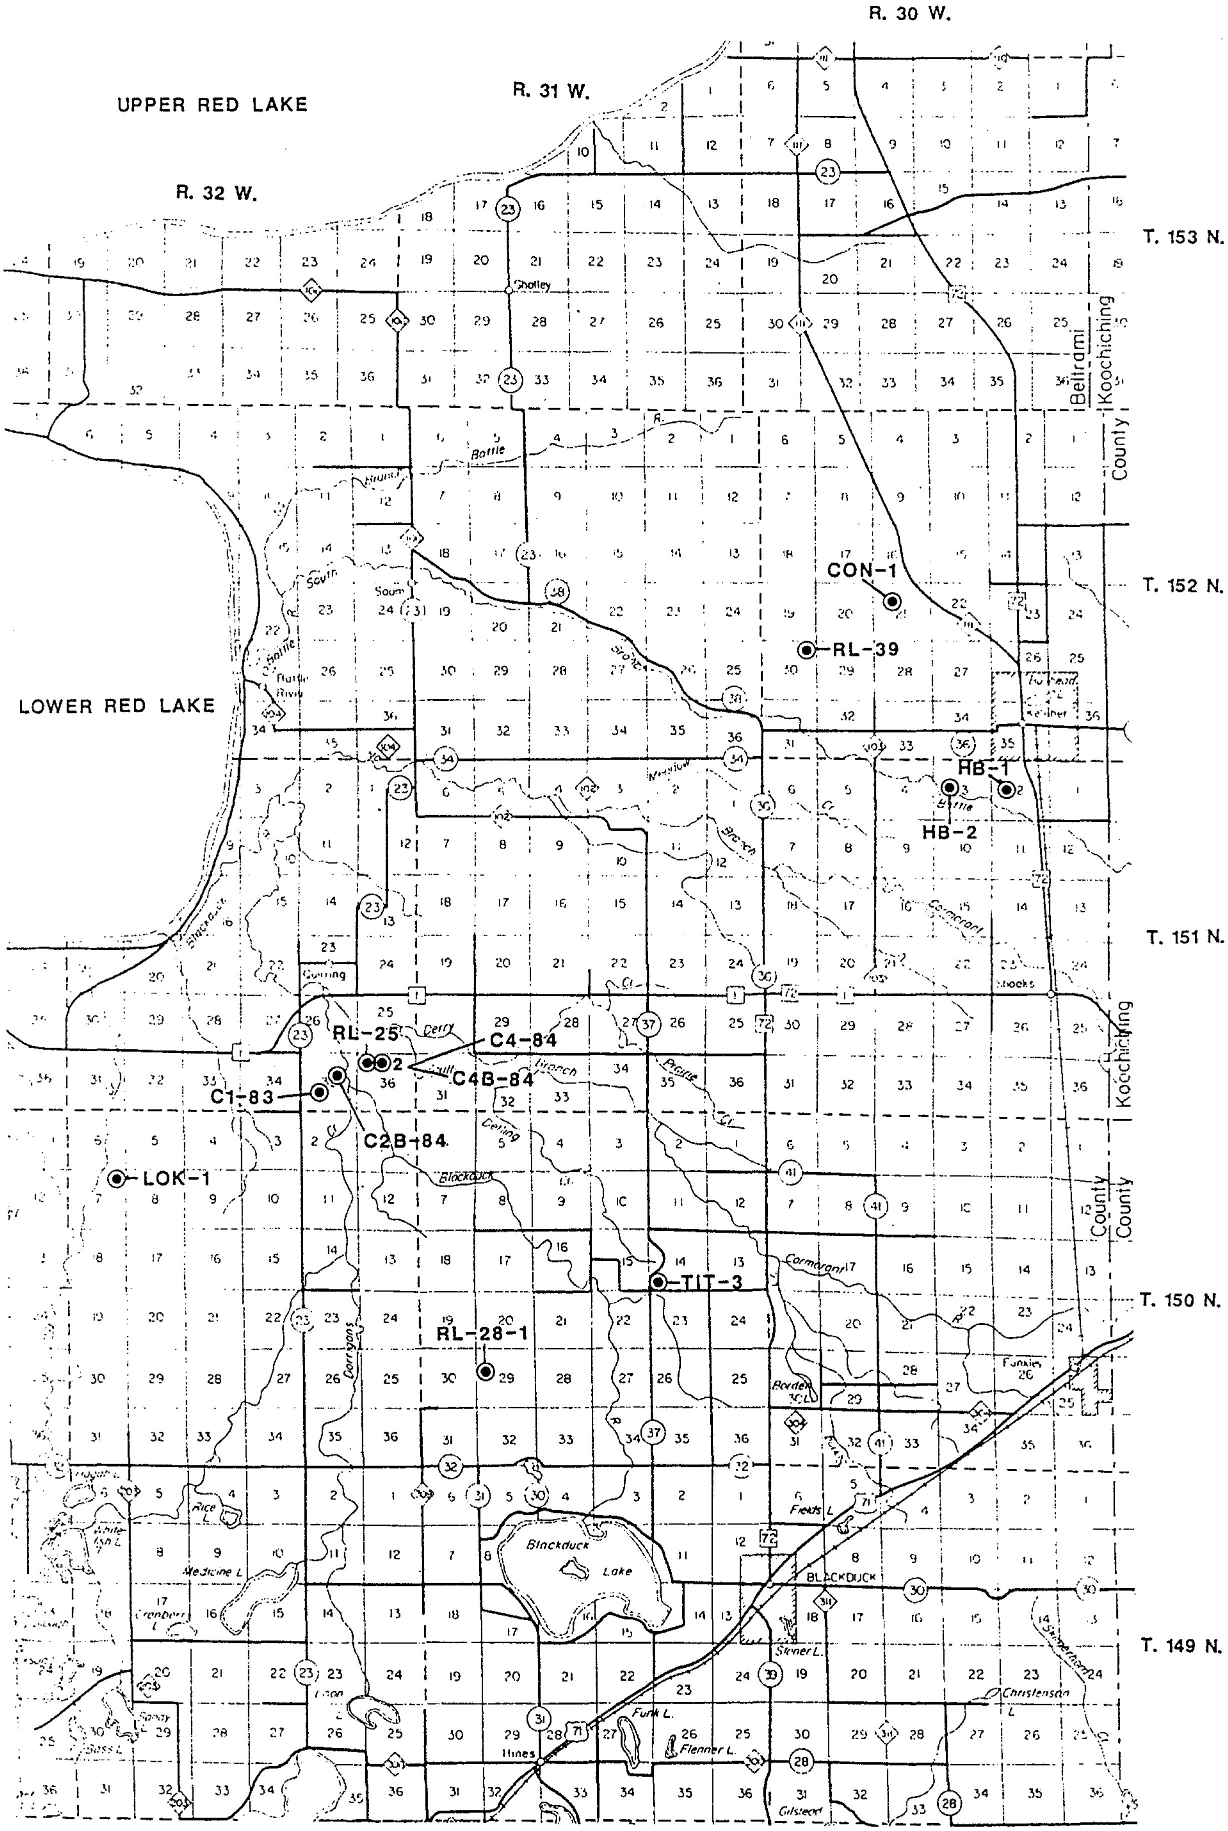
The next section of this report provides general background information about the area where the sampled drill holes were located.

The section on "Methodology of Sampling" discusses the pre-sampling work, the procedures, and the criteria used in sampling drill core. "Pre-sampling Work" also includes the preliminary data gathering and organizational information.

The next section then describes the contract analytical work including sample preparation and duplicate samples.

The section "Discussion of Results" includes the sample numbers vs. sample value plots and any comments concerning the actual rock samples or drill holes.

Lastly, a section on conclusions will close the body of the report; this is followed by the appendices.



0 1 2 3
MILES

◉ DESIGNATED DRILL HOLE

FIGURE 266-1

LOCATION, LAND OWNERSHIP, GENERAL ACCESSIBILITY, AND GENERAL GEOLOGY

The drill holes selected for sampling lie in Beltrami County, south and east of Red Lake in north-central Minnesota. This area is shown with the drill hole locations in Figure 266-1. The upper third of the area contains approximately 60% State of Minnesota land ownership, and 40% private ownership. The lower two thirds of the area is approximately 60% private ownership, with 30% county land, and 10% State of Minnesota land.

Access within the area on a year round basis is dependent on the road density which is quite variable. Wet, swampy ground in many parts, makes winter access a necessity. This is especially true in the north which is in the flat, ancient lake bed of Glacial Lake Agassiz.

The area falls within the undivided extension of the Wawa-Shebandowan volcano plutonic subprovince of the Superior Province. There are few outcrops in this portion of that granite-greenstone terrane, and overburden depths are typically 100 to 400 or more feet.

METHODOLOGY OF SAMPLING

One of the criteria for sampling these drill cores was that the drill holes could not be located in the proximity of currently leased state mineral lands, and therefore; it was necessary to plot drill hole locations on a current lease map.

The drill holes were then classified according to their distance from active State mineral leases. "A" classification meant **6 or more** miles between a drill hole and a current or proposed State lease. A "B" classification meant that the drill hole was **less than six miles** from current or proposed lease areas. A "C" classification is **in a proposed lease area,** but **greater than six miles** from active leases. A "D" classification is **in a proposed lease area,** but **1 to 6 miles** from active leases. An "E" classification is **less than a mile** from active leases.

After classification, all phases were directed first to holes designated "A" and then "B" and then "C" classifications. The number of drill holes found for each of the first 3 classifications were:

"A" = 187 drill holes

"B" = 72 drill holes

"C" = 82 drill holes.

For each of these drill holes a "Drill Hole Previous Sampling Inventory Sheet" (see Figure 266-2) was filled out with the following information:

1. Drill hole number
2. County
3. Section, Township, Range (Location)
4. Forty acre parcel (Location)
5. Whether a core or geophysical log was available
6. Footage of drill core
7. The number, footage interval, and analysis information
8. Indirect information (geophysical, geochemical work, geologic maps, etc.)
9. The date the sheet was filled out
10. The material to be examined

The analyses to be performed were generalized into the following groups:

Note: The abbreviation in parentheses (except those where the elements were listed as analyzed) were used on the sheets to identify the analyses performed.

PRECIOUS METALS - listed as analyzed (includes **Ru, Rh, Pd, Ag, Re, Os, Ir, Pt, Au**)

WHOLE ROCK (WR) - includes major oxides and also Na, Mg, K, Ca, Mn, Fe, Al, Si, P, Ti

RARE EARTH ELEMENTS (**REE**) - and associated elements: Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Ho, Er, Tm, Yb, Lu, Sc, Y, La

BASE METALS (BM) - includes Mg, Ti, Mn, Fe, V, Cr

URANIUM/THORIUM (U-TH) - listed as analyzed

TRACE ELEMENTS (TE) - include Li, Be, Rb, Sr

SULFUR (S) - listed as analyzed

Figure 266-3 shows a completed "Drill Hole Previous Sampling Inventory Sheet."

All of these sheets are now on open file at the Division of Minerals building in Hibbing, MN. The eventual intent is to integrate this data into the Minerals Database Project which is currently in development.

Because drill holes can have a wide variation in their sampling history, these sheets allow a quick determination of how much work has been done, and also how much is yet to be completed.

The drill holes initially chosen were located in Beltrami County. Drill holes are often clusered, and this area was no exception. The drill holes sampled are listed in Table 266-1

Pre-Sampling Work

All drill logs, analytical results, and other data were placed in open file for public examination on a monthly basis as they were received. This included the duplicate and standard sample analyses.

Sampling Procedures

The core for each drill hole was laid out in its entirety whenever possible. A general examination was made, after which temporary markers were used to indicate separate lithologic units and to mark areas of interest, including those to be sampled.

Drill core was examined in both wet and dry states; however, colors were recorded when it was wet. Color names were taken from the Geological Society of America Rock Color Chart. Core samples were sawed and bagged in accordance with the Department of Natural Resources core sampling procedures. A sample card containing the sampling information has been left within each interval. Some intervals are contained in more than one box, and consequently may appear to lack a sampling card if the wrong box is examined.

Sampling Criteria

The following criteria were used when selecting samples for analysis:

1. presence of sulfide or sulfosalt minerals;

2. presence of veining, especially with quartz, carbonate, sulfides;

3. chemical sediments such as cherts (especially with disseminated sulfides), iron formation (especially when sulfidized), carbonates (especially iron dolomites), tourmalinites, sulfides and graphitic rocks (?);

4. fractured-faulted intervals and adjacent rocks;

5. brittle-ductile deformation transitions;

6. lithologic contacts or transitions, including intrusive contacts;

7. oxidation-reduction, or other apparent chemical or process transitions;

8. unknown, dubious or unusual mineralogy or rock types.

The summarizing philosophy of this project was one of attempting to sample those intervals exhibiting the greatest variety of geologic processes.

A sample listing including the sample numbers, drillholes, footages and rock descriptions are given in Appendix A. During sample compositing, every attempt was made to keep the major lithotype of the subsamples the same.

SAMPLE PREPARATION AND ANALYSIS

Technical Service Laboratories, Ltd. (TSL) of Mississauga, Ontario was awarded the contract for sample preparation and the analytical work.

Sample Preparation

For a complete discussion of how samples were prepared and the procedures for handling duplicate and standard samples, see the sections "Sample Preparation" and "Analytical Work and Duplicate Samples" within Project 265.

Table 266-2 describes the analytical package used for greenstone - granite terrane rocks. The following abbreviations are used in this table:

% = percent (parts per hundred)

PPM = parts per million

PPB = parts per billion

FA = fire assay

ICP = inductively coupled plasma emission spectrometry

AA = atomic absorption

SP ION EL = specific ion electrode

WR = whole rock (inductively coupled argon plasma emission spectrometry)

INAA = instrumental neutron activation analysis

This table indicates the detection limits, the sample weight used, the analytical method, and the overlimit values for the elements (and some oxides) analyzed for. Overlimit value refers to the highest analytical value for which quality results can be produced for a given analytical method and element.

Table 266-2. ANALYTICAL PACKAGE FOR GREENSTONE-GRANITE TERRANE ROCKS, SOILS, AND OTHER GEOLOGIC MATERIALS.

ELEMENT	DETECTION LIMIT	SAMPLE WEIGHT grams	ANALYTICAL METHOD	OVERLIMIT VALUE

PRESENTATION AND DISCUSSION OF RESULTS

Appendix B contains a listing of the analytical results. These results are also displayed graphically in Figures 266-4, 266-5, 266-6, and 266-7 which are sample number vs. sample value plots.

The two high gold values (samples 21857 and 21858) were from drill hole RL25. These samples had previous been analyzed for gold and exhibited with high values, so our analyses were used as a "check" on TSL, and also to see how other elements varied with these samples.

These four figures indicate that the following elements also had "bumps" that were perhaps spatially related to Au "bumps": Bi, Sb, As, Ba (? weakly), S, Se, Ag, Cu, Mo, $Fe2O3$ (?), Pt, Pd, $Na2O$, B, $K2O$, Sr, and Rb. No one gold "bump" was associated with all the others.

One other apparently positive relationship noted in most the samples was between Li and Pd.

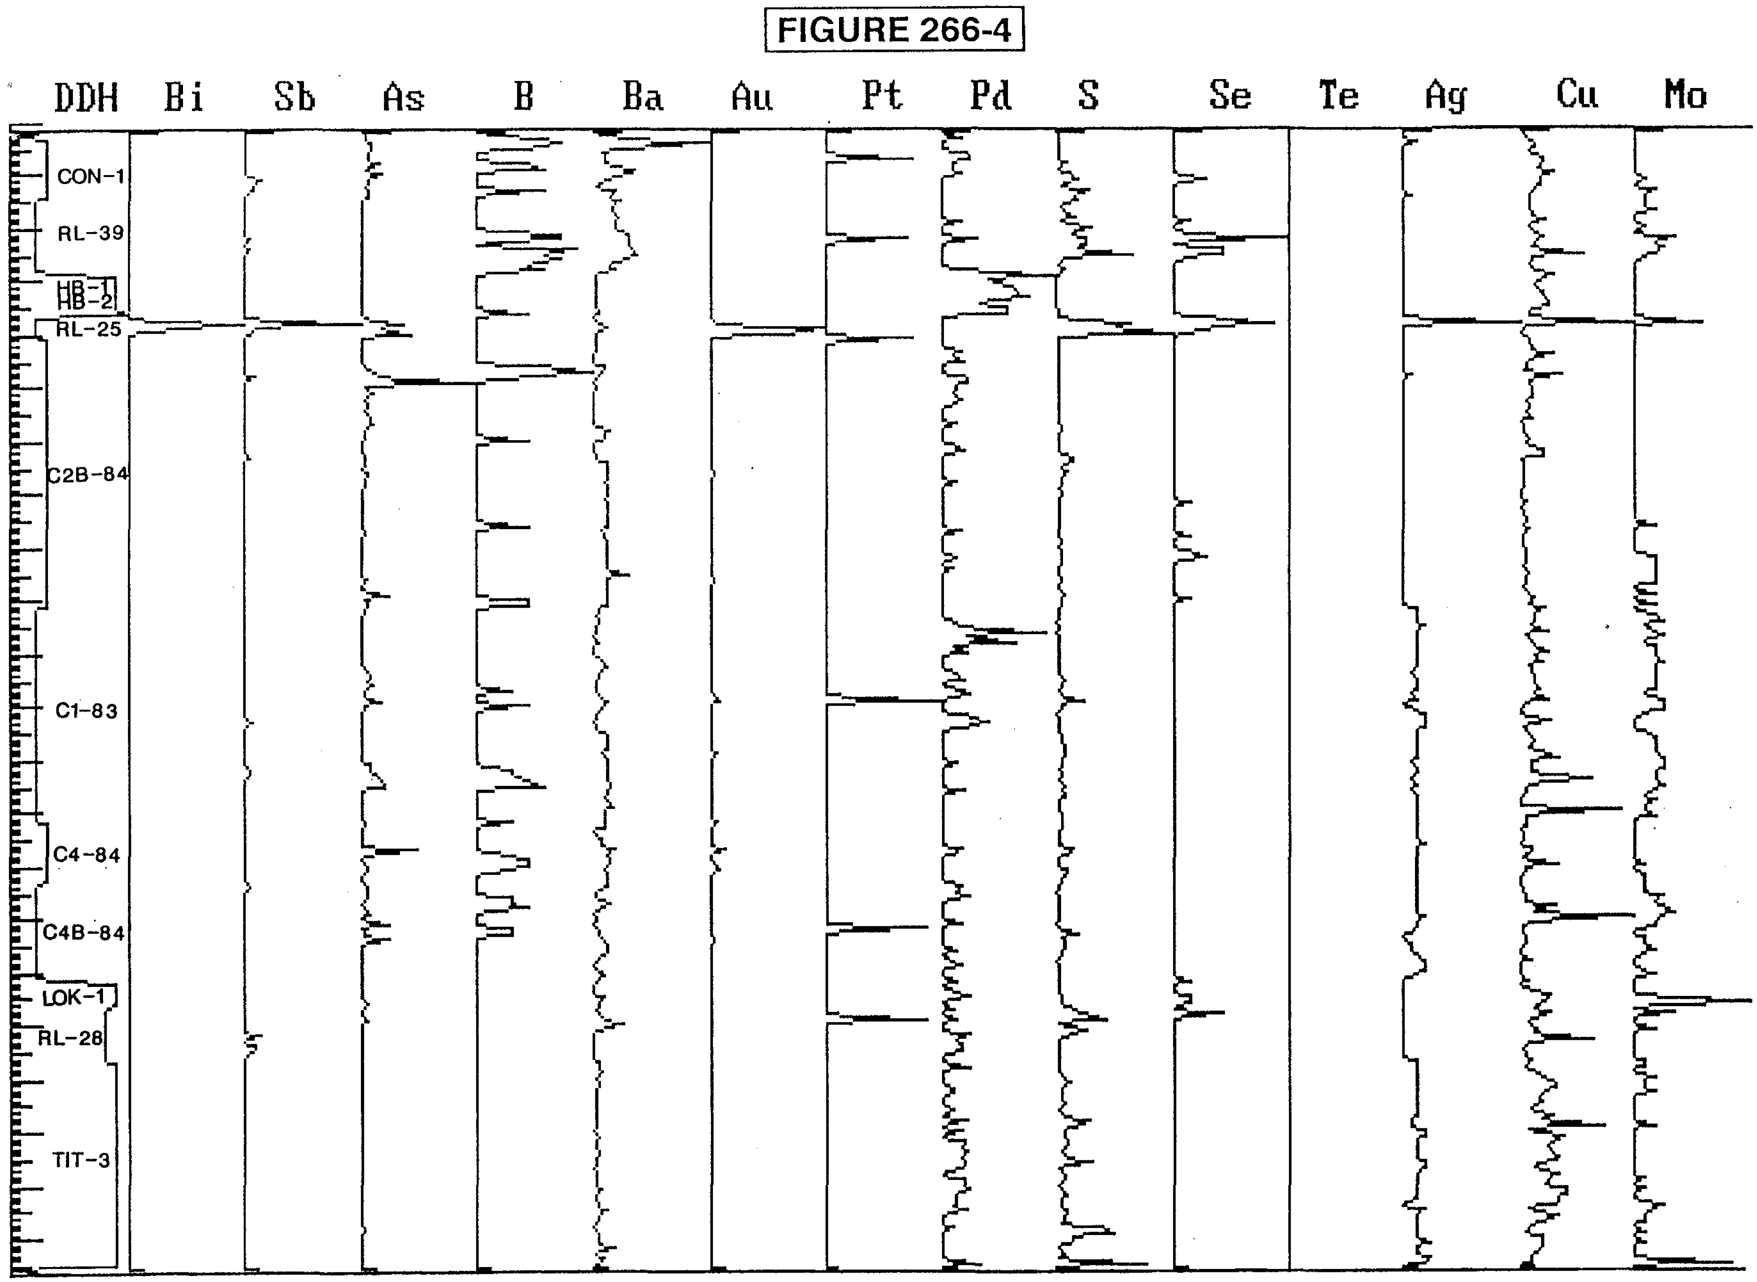

FIGURE 266-4: Sample Value vs. Sample # Plot for Archean Greenstone Sample Analyses (Bi, Sb, As, B, Ba, Au, Pt, Pd, S, Se, Te, Ag, Cu, Mo). Sample #'s are broken up by drill hole in the left column.

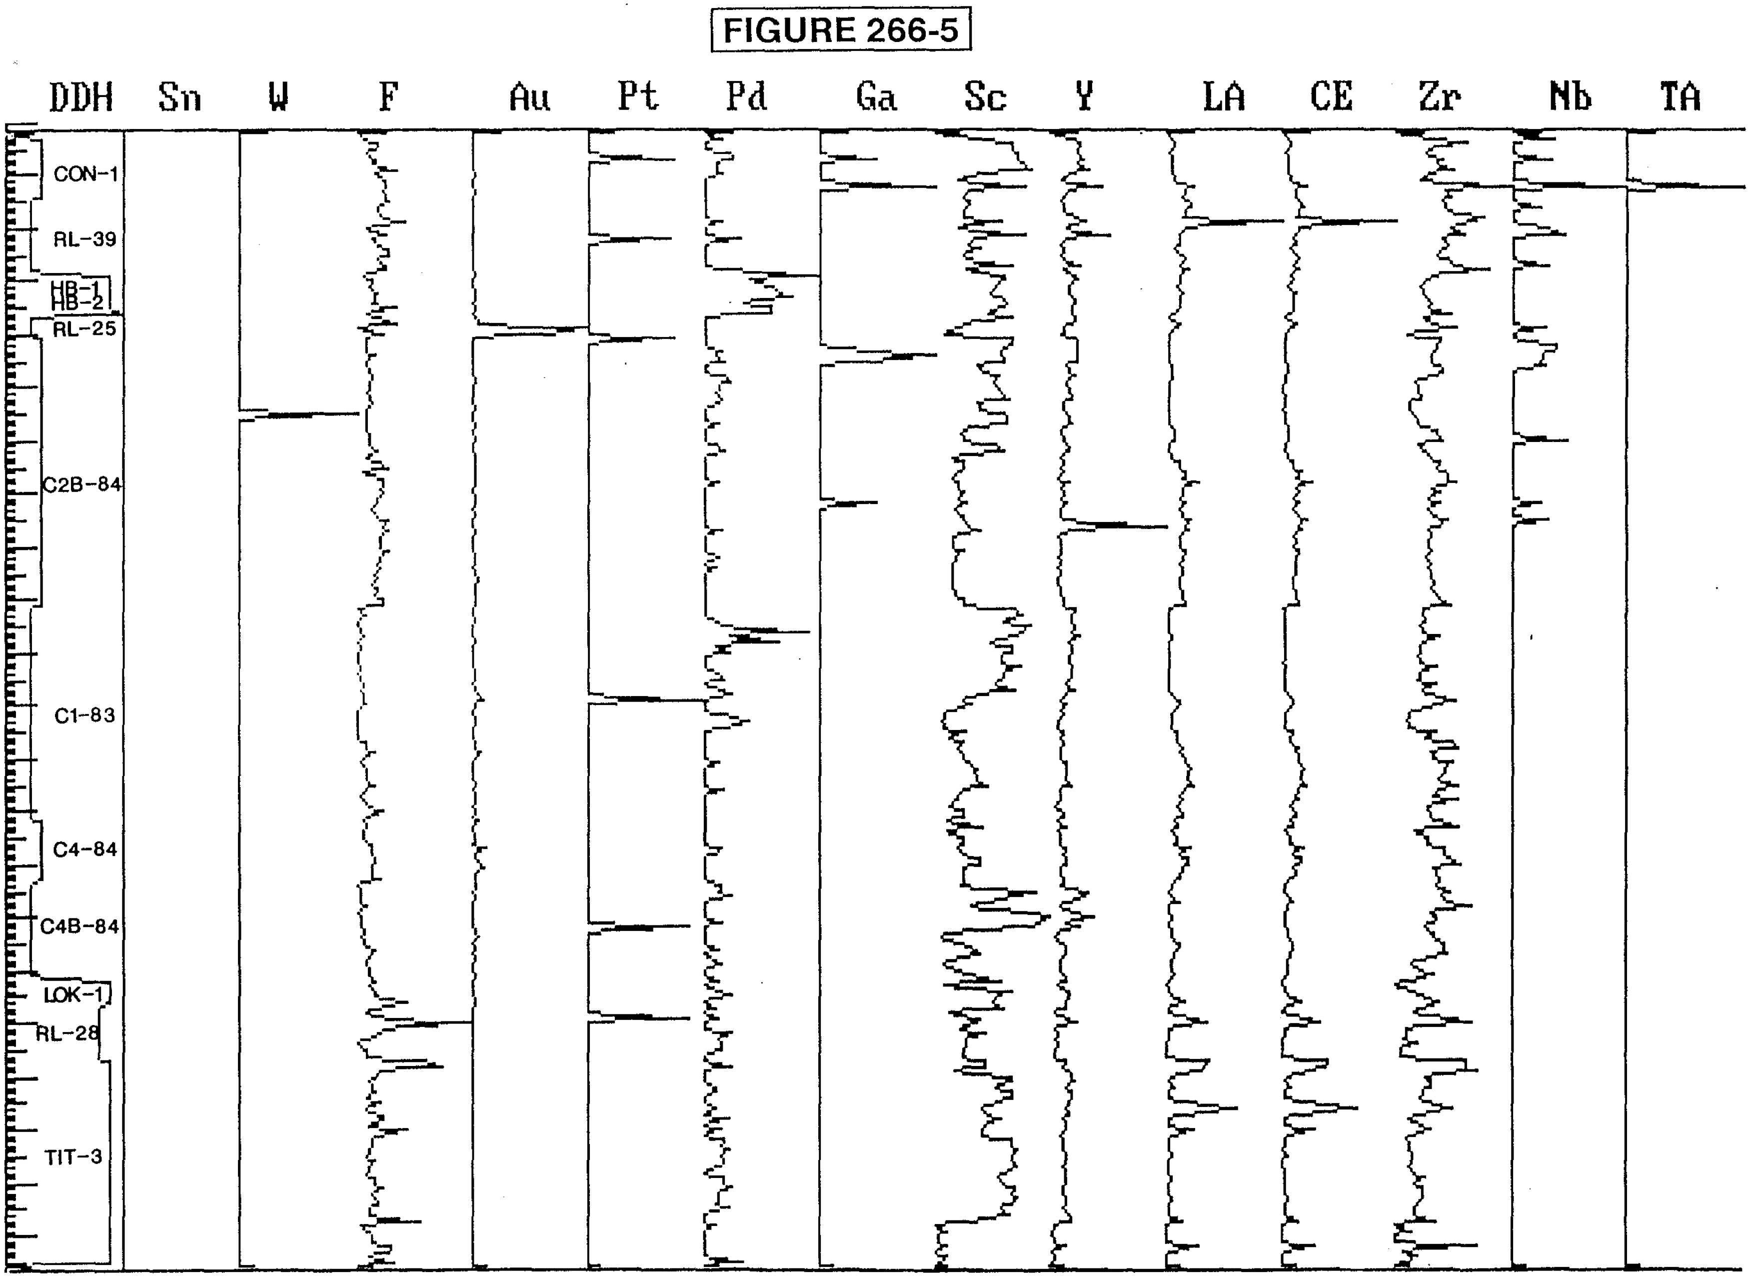

FIGURE 266-5: Sample Value vs. Sample # Plot for Archean Greenstone Sample Analyses (Sn, W, F, Au, Pt, Pd, Ga, Sc, Y, La, Ce, Zr, Nb, Ta). Sample #'s are broken up by drill hole in the left column.

FIGURE 266-6

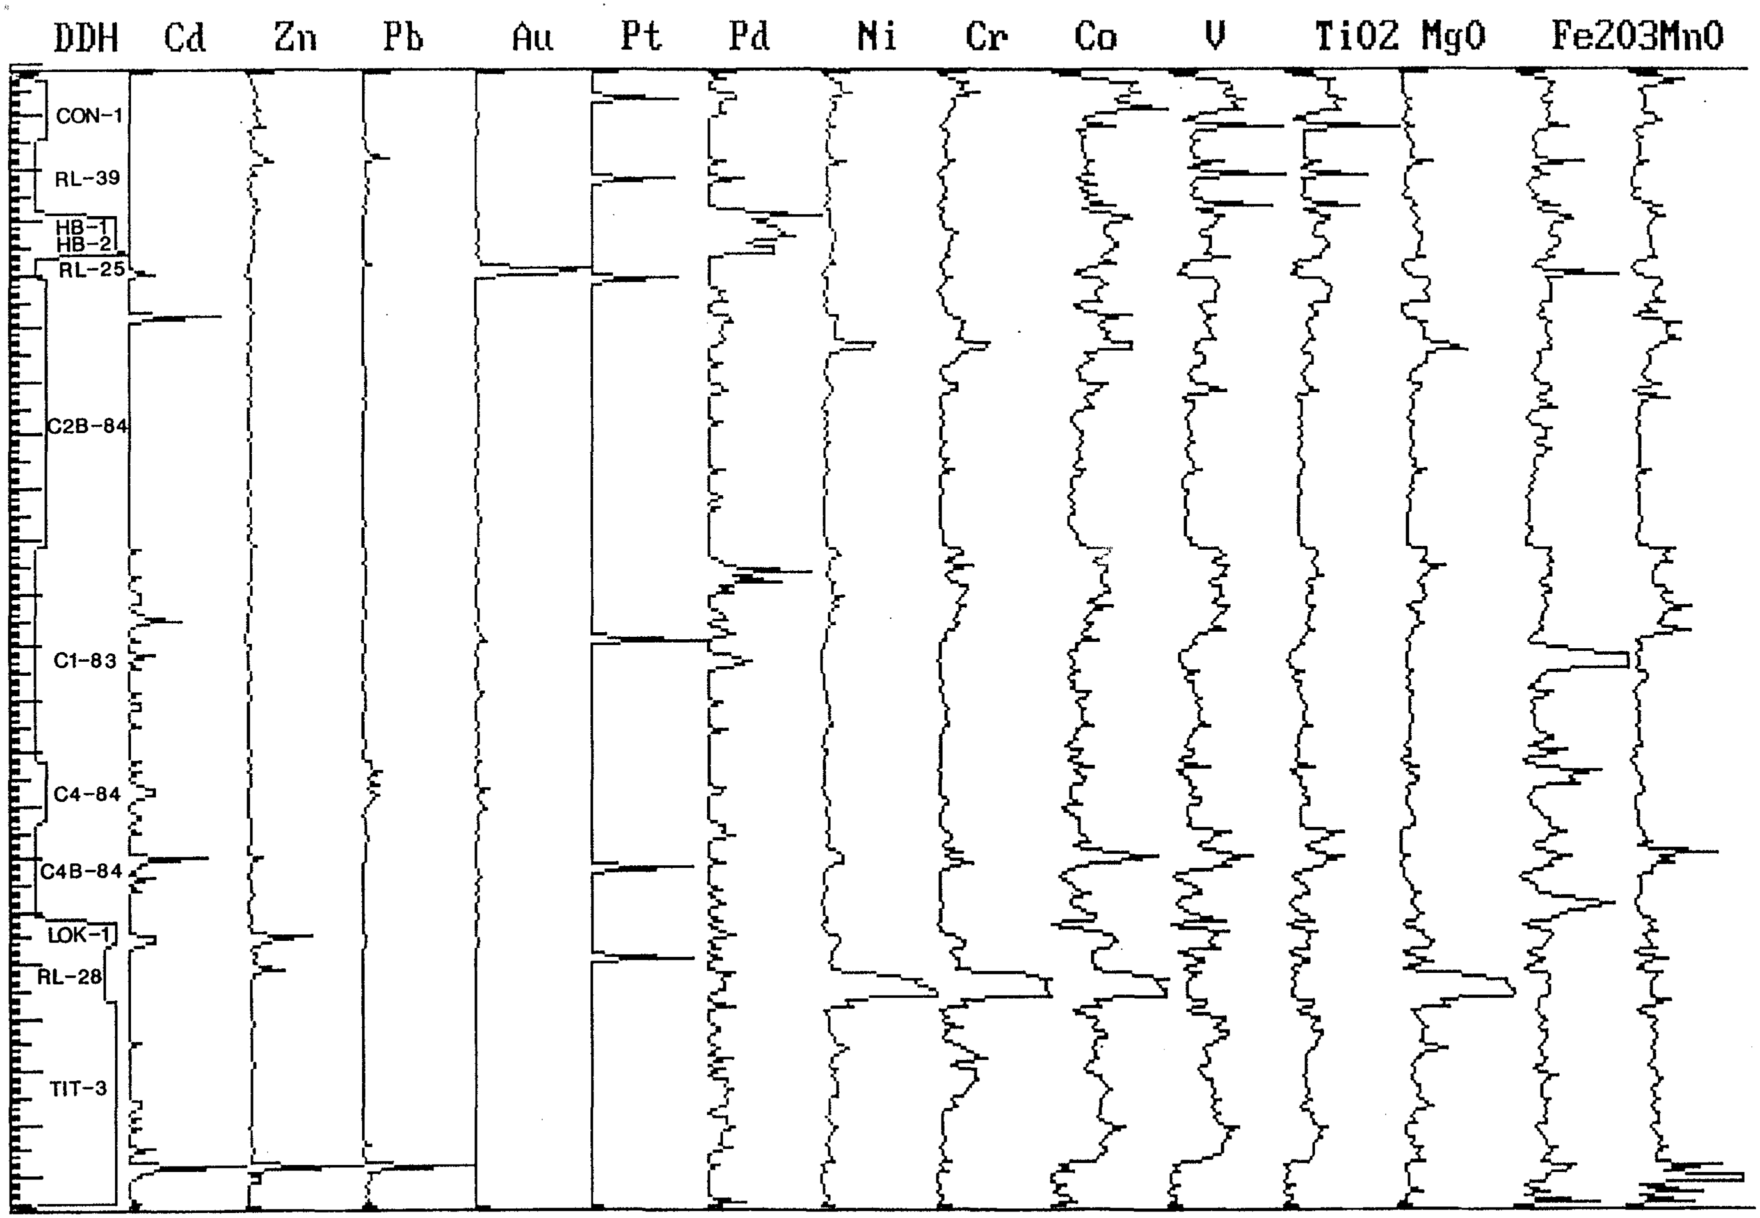

FIGURE 266-6: Sample Value vs. Sample # Plot for Archean Greenstone Sample Analyses (Cd, Zn, Pb, Au, Pt, Pd, Ni, Cr, Co, V, TiO2, MgO, Fe2O3, MnO). Sample #'s are broken up by drill hole in the left column.

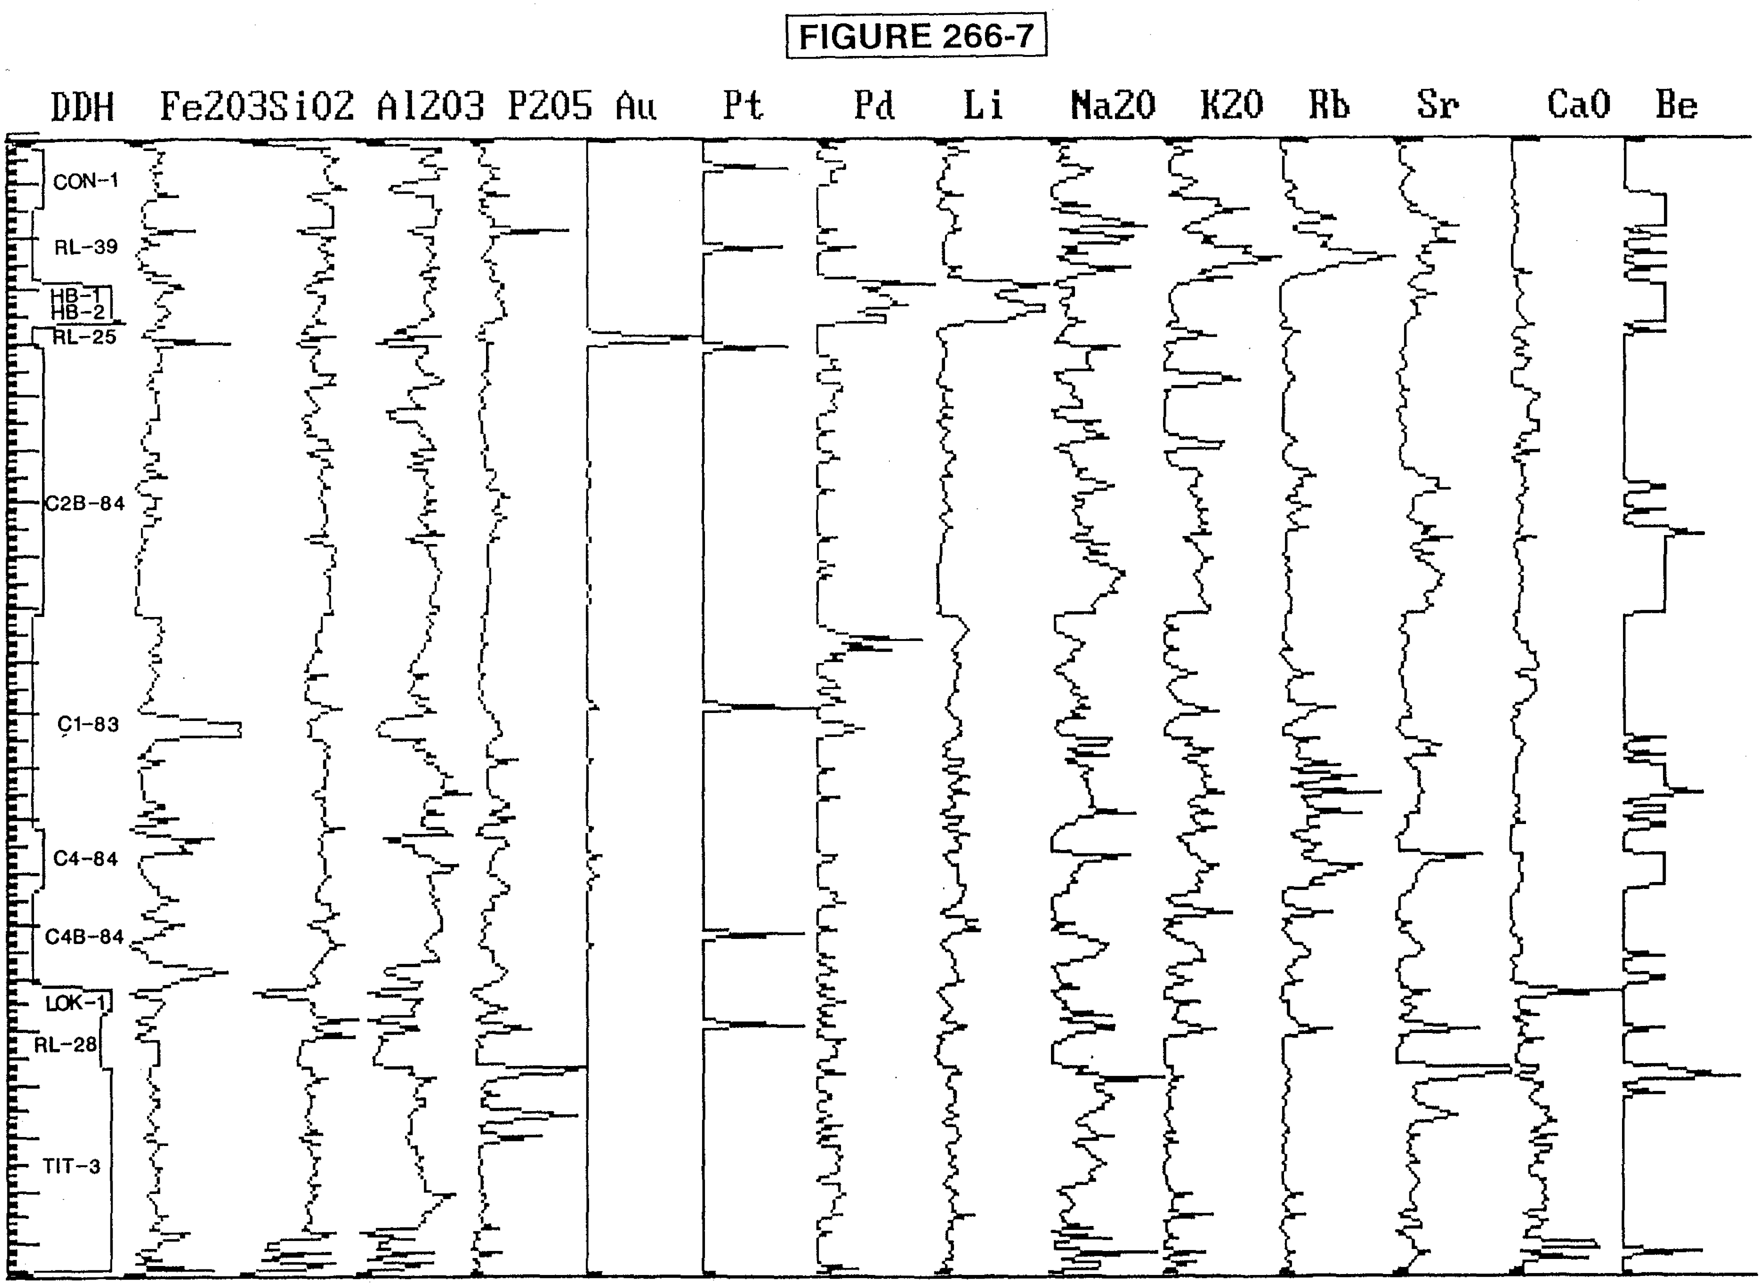

FIGURE 266-7: Sample Value vs. Sample # Plot for Archean Greenstone Sample Analyses (Fe2O3, SiO2, Al2O3, P2O5, Au, Pt, Pd, Li, Na2O, K2O, Rb, Sr, CaO, Be). Sample #'s are broken up by drill hole in the left column.

CONCLUSIONS

Of all the drill holes tested, only one had gold values above 1 ppm. Here Au was associated with Bi, Sb, As, Se, S, Ag, Cu, Mo and Fe2O3.

Samples in TIT-3 had low metal values, but one sample contained a chlorite-blackschist (ripidolite), sample number 22050. Unlike many massive sulfide blackschists, this one was quite calcareous.

ADDENDUM SHEET

REPORT 266
PAGE 264

We have two cores numbered HB-1 in our drill core library, one located in Beltrami County and the other located in Morrison County. The data in this report concerning **Drill Hole HB-1** applies to the core from Morrison County. The core from Beltrami County should have been used for this report but the core from Morrison County was inadvertently used.

We apologize for any inconvience this error may have caused.

C4B-84	22002		259.1-262		Dark reddish brown, foliated, weathered clay, saprolite.
	22003		262-265.1		Dark yellowish brown, phyllitic clay, saprolite with quartz vein.
	22004		265.1-270.5		Yellowish green clay, saprolite, locally foliated, with quartz vein.

PROJECT 266
SAMPLE LIST

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
C4B-84(cont.)	22005		270.5-284		
		22005-A		270.5-274	Grayish olive, locally foliated clay, saprolite; locally brecciated? quartz veins.
		22005-B		274-278	Yellow green, weathered clay altered crystal tuff? (saprolite).
		22005-C		278-284	Gray green to yellow green, locally phyllitic clay, saprolite.
	22006		295-304		Olive to reddish brown, locally phyllitic, locally layered, clay altered tuff with quartz veins.
	22007		309-322		Yellowish green to brown clay, saprolite? with crosscutting altered fractures, quartz veins.
	22008		330-335		Dark greenish gray, variably altered basalt to fine-grained gabbro with brown clayey margins, weakly magnetic.
	22009		364-371		Yellow green clay, saprolite, with brown limonitic spots, quartz veins.
	22010		402-413		Brown, locally foliated, clay altered tuff with quartz-carbonate veins, weathered pyrite cubes.
	22011		421-428		
		22011-A		421-425	Dark gray, tuff with lapilli & bombs, with quartz veins, locally much pyrite in veins & disseminated (0-10%).
		22011-B		425-428	Dark gray, locally foliated tuff with lapilli & bombs, quartz-carbonate? veins, local pyrite in veins.

PROJECT 266
SAMPLE LIST

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
C4B-84(cont.)	22012		491-495		Gray, phyllitic, tuff with quartz lenses/layers (30%), with local carbonate, local limonite.
	22013		581.1-597		
		22013-A		581.1-585	Green gray, locally phyllitic, locally laminated calcareous tuff with quartz-calcite veins, disseminated pyrite.
		22013-B		585-589	Gray green to yellow green, phyllitic tuff, locally calcareous, with quartz-calcite veins.
		22013-C		589-593	Green gray, locally calcareous, phyllitic tuff with few quartz-calcite veins, disseminated pyrite.
		22013-D		593-597	Green gray to light gray, calcareous, phyllitic tuff with disseminated pyrite, quartz-calcite veins - laminae.
	22014		603-609		Green gray, phyllitic, locally calcareous tuff with quartz-calcite veins, pyrite in veins.
	22015		617.5-621		Green gray, phyllitic tuff with local lamination, few thin quartz veins.
	22016		622-624.5		Dark green to red brown, locally calcareous interlaminated hematite, magnetite, & green phyllite.
	22017		624.5-628.5		Reddish black, laminated magnetite & hematite with few green phyllite laminae, few quartz-calcite veins, hematite in shear.

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
C4B-84(cont.)	22018		628.5-643		
		22018-A		628.5-633	Dark green gray, laminated, phyllitic tuff with magnetite, pyrite in layer, quartz-calcite vein.
		22018-B		633-638	Dark green gray, laminated, phyllitic, tuff with decreasing magnetite, minor quartz-calcite veins, disseminated pyrite.
		22018-C		638-643	Dark gray green, locally laminated, phyllitic tuff with decreasing crystalline magnetite, hematite in fractures, disseminated pyrite, few quartz-calcite veins.
	22019		643-649		Dark gray green, phyllitic tuff with local calcite, decreasing magnetite, hematite in fracture, minor quartz-calcite vein.
LOK-1	21852		270-280		Andesite flow with quartz-calcite veins.
	21865		282-282.3		4" thick calcite vein in andesite flow.
	21853		350-360		Tuff with chlorite alteration, weakly fractured.
	21854		582-587		Schistose graphitic argillite.
	21855		622-627		
		21855-A		622-624	Graphite schist.
		21855-B		624-625.5	Biotite schist with chlorite & talc alteration.
		21855-C		625.5-627	Chloritic altered tuff.
RL-28	21889		293-302.5		Clay altered gabbro.
	21877		385-388		Graphitic slate & calcite veins.
	21878		388-389		Chlorite & talc altered gabbro.

PROJECT 266
SAMPLE LIST

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
RL-28(cont.)	21879		389-390.5		Chlorite altered gabbro-chlorite schist.
	21880		624.5-637		Graphitic metasediments with calcite & pyrite veins.
	21881		637-641		Chlorite schist with calcite layers & lenses.
	21882		761-770.5		Calcareous ultramafic dike, slight alteration to chlorite.
	21886		780.5-790		Medium-grained ultramafic, slight alteration to chlorite.
	21887		926.5-936		Calcareous ultramafic, chlorite alteration.
	21888		936-946		Chlorite altered calcareous ultramafic.
TIT-3	22020		206-216		Dark gray green, basalt - andesite? with carbonate veins (siderite?).
	22021		233-248		
		22021-A		233-234.7	Green gray, basalt - andesite?
		22021-B		235-236	Green gray, basalt - andesite?
		22021-C		239-240	Green gray, basalt - andesite with clay? in fractures.
		22021-D		247-248	Green gray, basalt - andesite? with carbonate veins.
	22022		234.7-247		
		22022-A		234.7-235	Pink andesite? porphyry with pyroxene phenocrysts.
		22022-B		236-239	Pink andesite? porphyry with pyroxene phenocrysts.
		22022-C		240-247	Purple pink, andesite? porphyry with pyroxene phenocrysts, epidote? altered fractures.
	22023		290-299		Green to dark gray green, basalt - andesite? with many thin calcite veins, disseminated pyrite.

PROJECT 266
SAMPLE LIST

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
TIT-3(cont.)	22024		305-316.8		Dark gray green, basalt - andesite? with calcite & siderite? veins, disseminated pyrite.
	22025		316.8-318.5		Gray (pink), chlorite altered, diabase with few thin calcite veins.
	22026		336-347		
		22026-A		336-342	Dark gray green, basalt - andesite with quartz-carbonate veins, local pyrite (0-5%).
		22026-B		342-347	Dark gray green, locally fractured basalt - andesite? with quartz-carbonate (siderite?) veins.
	22027		347-359		
		22027-A		347-352	Dark green, locally foliated basalt - andesite? with many thin carbonate veins, disseminated pyrite.
		22027-B		352-359	Dark green, tuff with local lapilli?, calcite - siderite? veins, disseminated pyrite.
	22028		359-371		
		22028-A		359-365.4	Green, basalt - andesite? with thick & many thin calcite veins, local chlorite on vein walls, disseminated pyrite.
		22028-B		365.4-371	Green, basalt - andesite? with calcite - carbonate (siderite) veins, local disseminated pyrite.
	22029		371-386		
		22029-A		371-378	Gray green tuff? with (50%) carbonate veins.
		22029-B		378-386	Gray green tuff? with local (15%) carbonate veins.

TIT-3(cont.)	22030		386-396		
		22030-A		386-389	Dark gray green, basalt - andesite? with (20%) carbonate veins, local foliation.
		22030-B		389-393	Gray green, basalt - andesite? with amygdales? (5-20%) decreasing carbonate veins.
		22030-C		393-396	Yellow green to gray green, basalt - andesite? with decreasing amygdales, local foliation, (5%) carbonate veins.
	22031		404-408		Gray green to green gray, locally silicified basalt - andesite? with calcite-siderite? veins, local amygdales, pyrite & pyrrhotite in layer.
	22032		408-413		Green gray to gray, basalt - andesite? with (5%) pyrite disseminated & layers, quartz-calcite veins with siderite?
	22033		413-415.5		Gray to grayish brown, locally silicified basalt - andesite? with (20%) thin calcite veins, local pyrite zones & pyrrhotite?
	22034		415.5-424		
		22034-A		415.5-420	Dark gray, basalt - andesite with increasing layers of magnetite, pyrite in zones, & many thin calcite veins.
		22034-B		420-424	Dark green gray, basalt - andesite with local layers of magnetite, pyrite in zones, calcite in layers & veins.

293

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
TIT-3(cont.)	22035		436-461		
		22035-A		436-441	Green to dark gray green, basalt - andesite? with layers of magnetite, disseminated pyrite, pink carbonate & calcite veins.
		22035-B		441-446	Olive to dark green, mottled chlorite, epidote altered basalt - andesite? with magnetite layers, few carbonate veins, & pyrite in layers.
		22035-C		446-451	Olive to dark green, mottled epidote and chlorite, altered basalt - andesite? with carbonate veins, pyrite in veins, quartz-carbonate layers, magnetite layers.
		22035-D		451-456	Olive to dark green, mottled basalt - andesite with layers of magnetite, few carbonate veins, small amount. disseminated pyrite.
		22035-E		456-461	Olive to dark green, mottled epidote & chlorite altered basalt - andesite? with quartz-carbonate layers, disseminated pyrite, magnetite layers.
	22036		461-486		
		22036-A		461-466	Olive to dark green, mottled epidote & chlorite altered basalt - andesite? with decreasing magnetite layers, calcite layers, pink carbonate veins.

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
TIT-3(cont.)	22036(cont.)		461-486		
		22036-B		466-471	Olive to dark green, mottled epidote & chlorite alt basalt - andesite? with few dark magnetite layers, carbonate veins, disseminated pyrite.
		22036-C		471-476	Green to gray, mottled basalt - andesite? dark layers - magnetic, few calcite veins with pink carbonate, local disseminated pyrite.
		22036-D		476-481	Dark gray green, basalt - andesite? with decreasing magnetite layers, few carbonate veins.
		22036-E		481-486	Gray green, "grainy" basalt - andesite, with local magnetite layers, carbonate layers & veins, local disseminated pyrite.
	22037		497-509		
		22037-A		497-504	Dark green gray, locally siliceous, basalt - andesite? with quartz-carbonate veins, crystalline magnetite in vein, pyrite in layer.
		22037-B		504-509	Dark green gray, locally (yellow green) siliceous, basalt - andesite? with thin calcite veins, local amygdales?
	22038		509-522		
		22038-A		509-516	Gray to green gray, locally (yellow-green) siliceous basalt - andesite? with local amygdales?, quartz-calcite-carbonate veins, pyrite in layers.

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
TIT-3(cont.)	22038(cont.)		509-522		
		22038-B		516-522	Green gray to yellow green, basalt - andesite?; with quartz-calcite-carbonate veins, disseminated pyrite, 1' dike.
	22039		522-535		
		22039-A		522-529	Yellow green to green gray, locally siliceous, basalt - andesite? with disseminated pyrite, quartz-calcite-pink carbonate veins.
		22039-B		529-535	Dark green gray, basalt - andesite? with (1-10%) disseminated pyrite, thin calcite layers with local pyrite.
	22040		569.5-572		Gray, basalt - andesite? with pyrite in veins, few thin calcite veins.
	22041		593-604		Olive to gray green, mottled altered basalt - andesite? with magnetite layers, calcite veins & quartz, disseminated pyrite.
	22042		614-627		Dark green gray, basalt - andesite? with local magnetite layers, local tan silicified tuff, quartz-calcite veins, disseminated pyrite.
	22043		640-646		Green gray to yellow green, locally silicified, basalt - andesite? with local disseminated pyrite, quartz-calcite & siderite? veins.
	22044		646-655		
		22044-A		646-650	Pale olive, altered - silicified tuff - andesite? with many thin red carbonate veins, local pyrite, quartz veins - blebs.

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
TIT-3(cont.)	22044(cont.)		646-655		
		22044-B		650-655	Pale olive to light gray, altered silicified tuff - andesite? with local quartz-calcite veins - orange stain? local shear?, local pyrite.
	22045		655-671		
		22045-A		655-663	Pale olive to gray green, locally more siliceous, andesite? with disseminated pyrite, quartz veins with calcite.
		22045-B		663-671	Olive to gray green, locally silicified andesite? with thick quartz veins (4") with carbonate, disseminated pyrite.
	22046		671-680.1		
		22046-A		671-675	Olive to gray, locally silicified andesite? with few quartz-calcite veins with orange?, disseminated pyrite.
		22046-B		675-680.1	Dark green gray, locally silicified (yellow-green), calcareous andesite? with few calcite veins, disseminated pyrite.
	22047		686.1-698		
		22047-A		686.1-692	Olive to green gray, mottled, calcareous basalt - andesite? with calcite veins, disseminated pyrite.
		22047-B		692-698	Olive to green gray, locally silicified, calcareous basalt - andesite? with quartz-calcite veins with orange stain?, disseminated pyrite.

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
TIT-3(cont.)	22048		698-701		Dark green gray, locally calcareous basalt - andesite? with (5%) quartz-calcite veins with orange stain? disseminated pyrite.
	22049		701-713		
		22049-A		701-707	Dark green gray, basalt - andesite? with disseminated pyrite, few quartz-calcite veins with local orange stain?
		22049-B		707-713	Dark green gray to grayish olive, basalt - andesite? with many thin quartz-calcite veins, disseminated pyrite.
	22050		713-719		Fine to medium grained, gray chlorite - calcite alteration rock; in calcareous - siliceous - tuff or chert host with minor quartz-calcite veins, disseminated pyrite. (Massive sulfide "blackschist" type alteration.)
	22051		746-756		Gray, quartz - magnetite - sulfide iron formation with calcite veins, minor pyrite, pyrrhotite, Galena, Sphalerite, chalcopyrite.
	22060		759-763		Dark gray, quartz-magnetite-sulfide iron formation, with few calcite veins; 30% pyrrhotite, pyrite, chalcopyrite.
	22052		781.3-785		Dark gray green, locally calcareous, locally siliceous, chlorite iron formation with local magnetite, garnet zones, disseminated pyrite.

DDH	SAMPLE #	SUBSAMPLE #	OVERALL SAMPLE FOOTAGE	SUBSAMPLE FOOTAGE	LITHOLOGY
TIT-3(cont.)	22053		796-804		Pale gray to gray, locally siliceous marble? with chlorite streaks, disseminated pyrite, calcite veins.
	22054		804-818.5		Reddish brown, calcareous syenite porphyry with 40% pink K-feldspar? phenocrysts, few thin calcite veins.
	22055		818-5-821		Gray, siliceous marble? with a few local magnetite, calcite veins, dark lined fractures with pyrite.
	22056		821-828.5		Grayish olive, siliceous tuff with thin quartz-calcite veins, foliation?, orange stain in some veins.
	22057		828.5-836		Dusky yellow green, siliceous tuff with few quartz-calcite veins, with orange stain locally.

LOGGER PROFILES

These profiles were created using the Logger Program (version 2) by RockWare Inc. The set included here covers just 1 drill hole, BA-4. The profiles for the rest of the drill holes sampled for Project 255-1 are available as open file material from the DNR Minerals Division, Hibbing, MN.

The first four pages are an index of the patterns used in the Lithology, Sulfide Mineralization, and Alteration Columns. The cover sheet of the profiles is then a small scale logger profile, without lithologic descriptions, of the entire hole. Areas of interest can then be examined at on a larger scale in the remaining pages.

The scales of the chemical analyses histograms are consistant throughout all of the drill hole profiles, with the upper limit determined from the largest analysis value of that particular element. The upper limits are as follows:

SiO2	72.85 %
Al2O3	27.59 %
CaO	19.44 %
MgO	29.66 %
Na2O	6.06 %
K2O	11.55 %
Fe2O3	49.00 %
TiO2	28.72 %
P2O5	3.90 %
Cr	12,186 ppm
V	2,786 ppm
Au	318 ppb
S	52.96 %
Cl	840 ppm
Ni	10,000 ppm
Cu	10,000 ppm
Pt	473 ppb
Pd	887 ppb
Ag	6.8 ppm
Percent Oxides	100 %

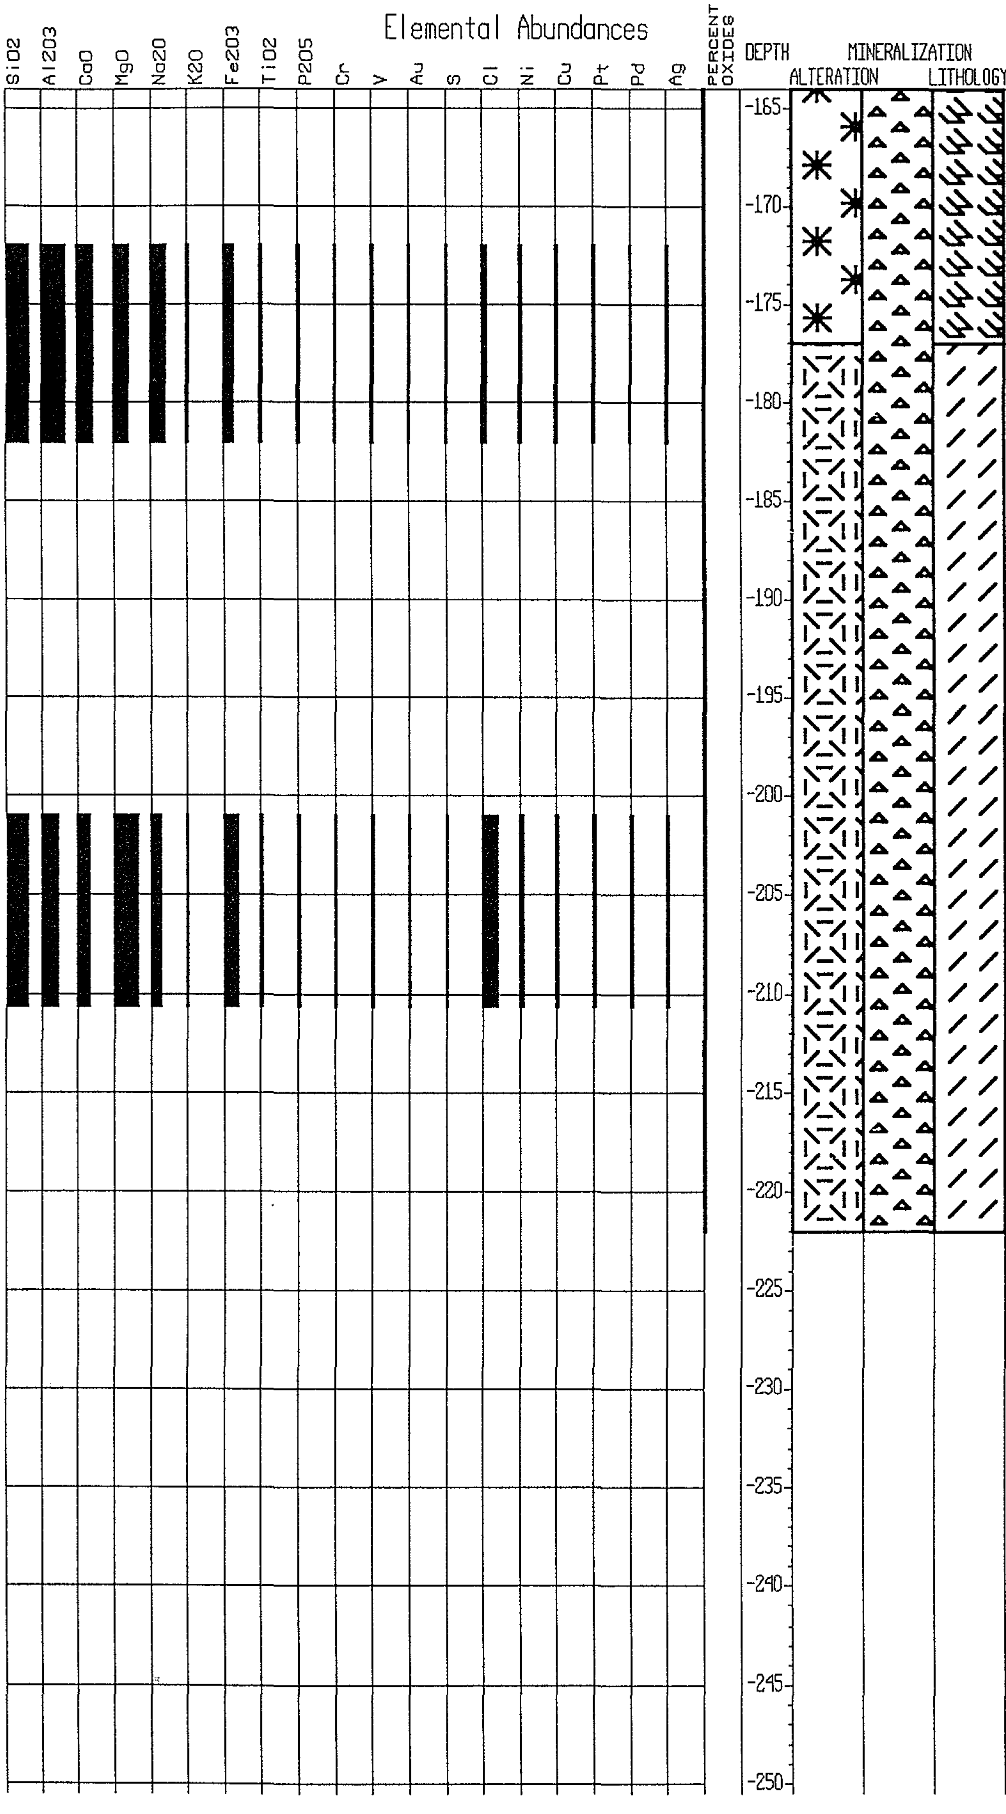
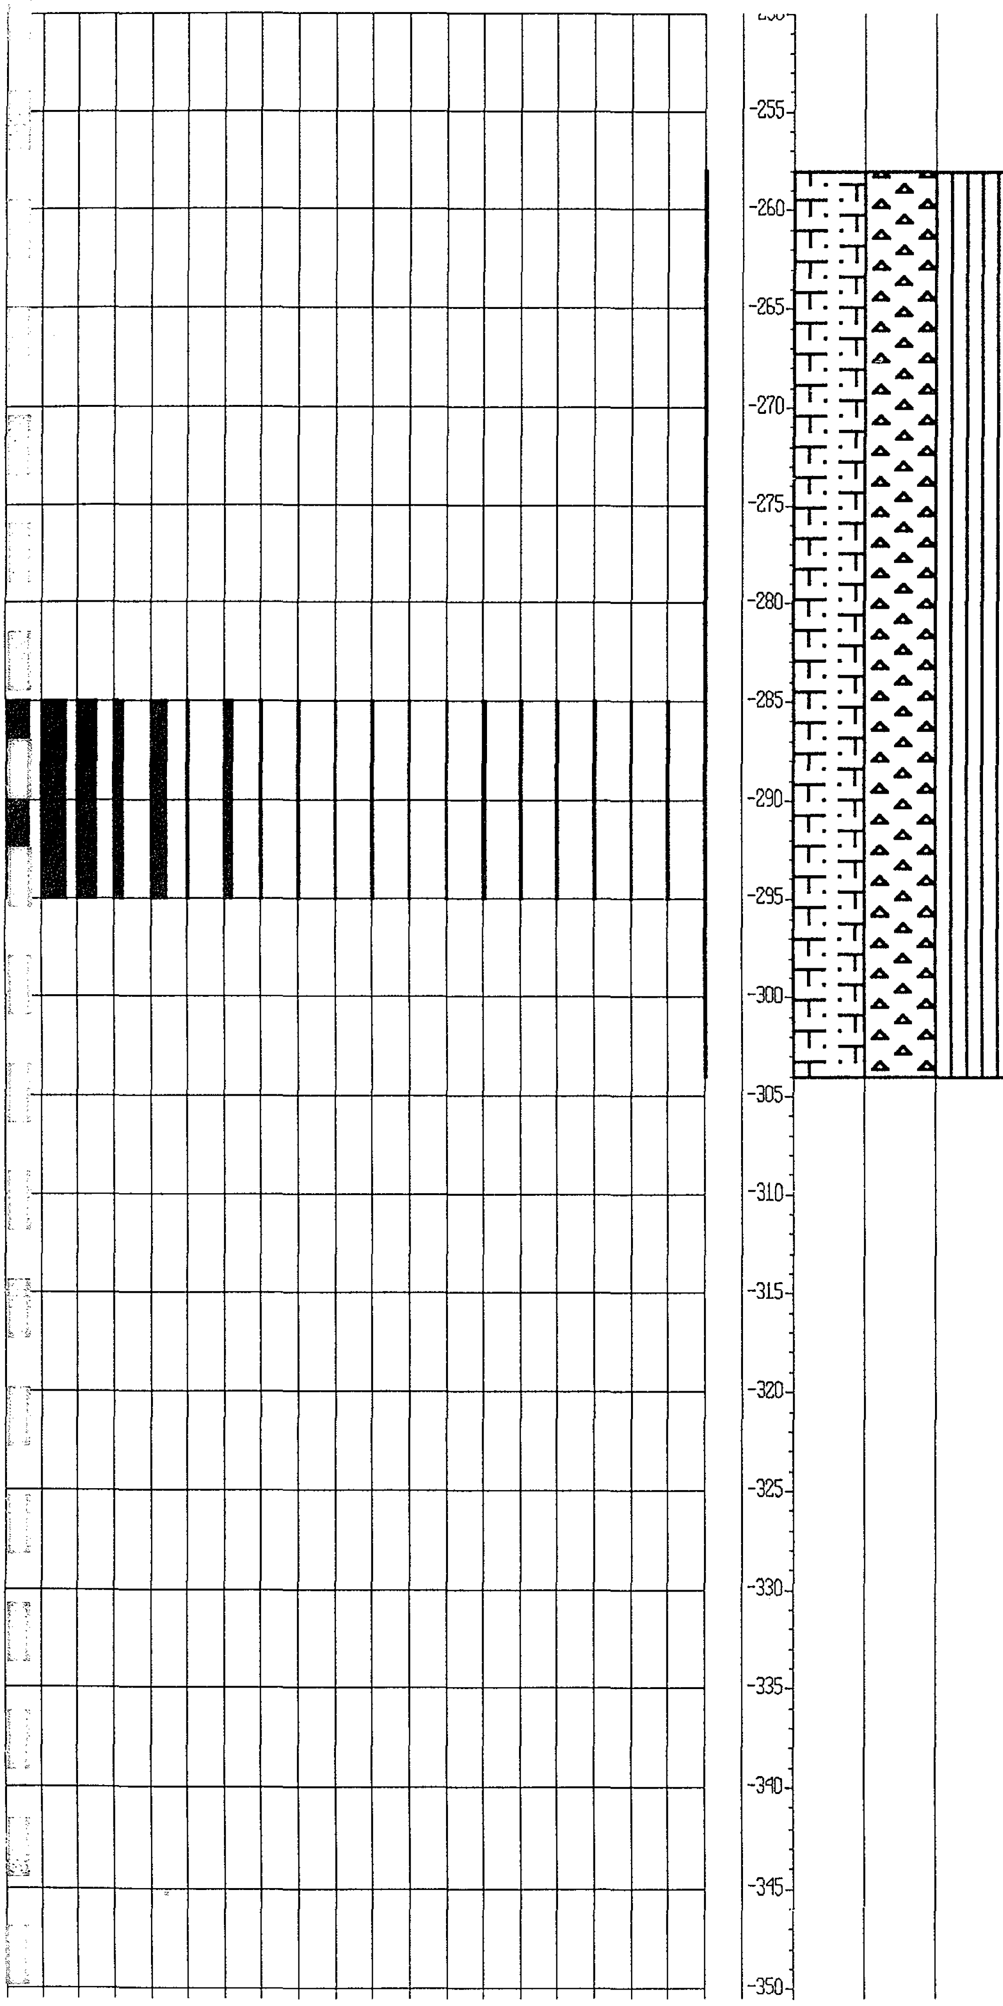
DDH BA-4 PART 1



DESCRIPTIONS/COMMENTS

Lt-grn-grey, cgr, anortc-Troct. Locly pegmtdl.

Dark green, cgr, serpent-Picr. w/ a few pods lenses of Anorth. The core surface is locally covered w/ rusty-red-colored drops.



Grey, pegmtdl, anortc-ol-Gabb pyxs occur as very large discrete grns and also as minor oiks, ol as large 5-20mm aggregates. Unite quite inhomo w/ sections of pegmtc (Anorth tract and Gabbr).

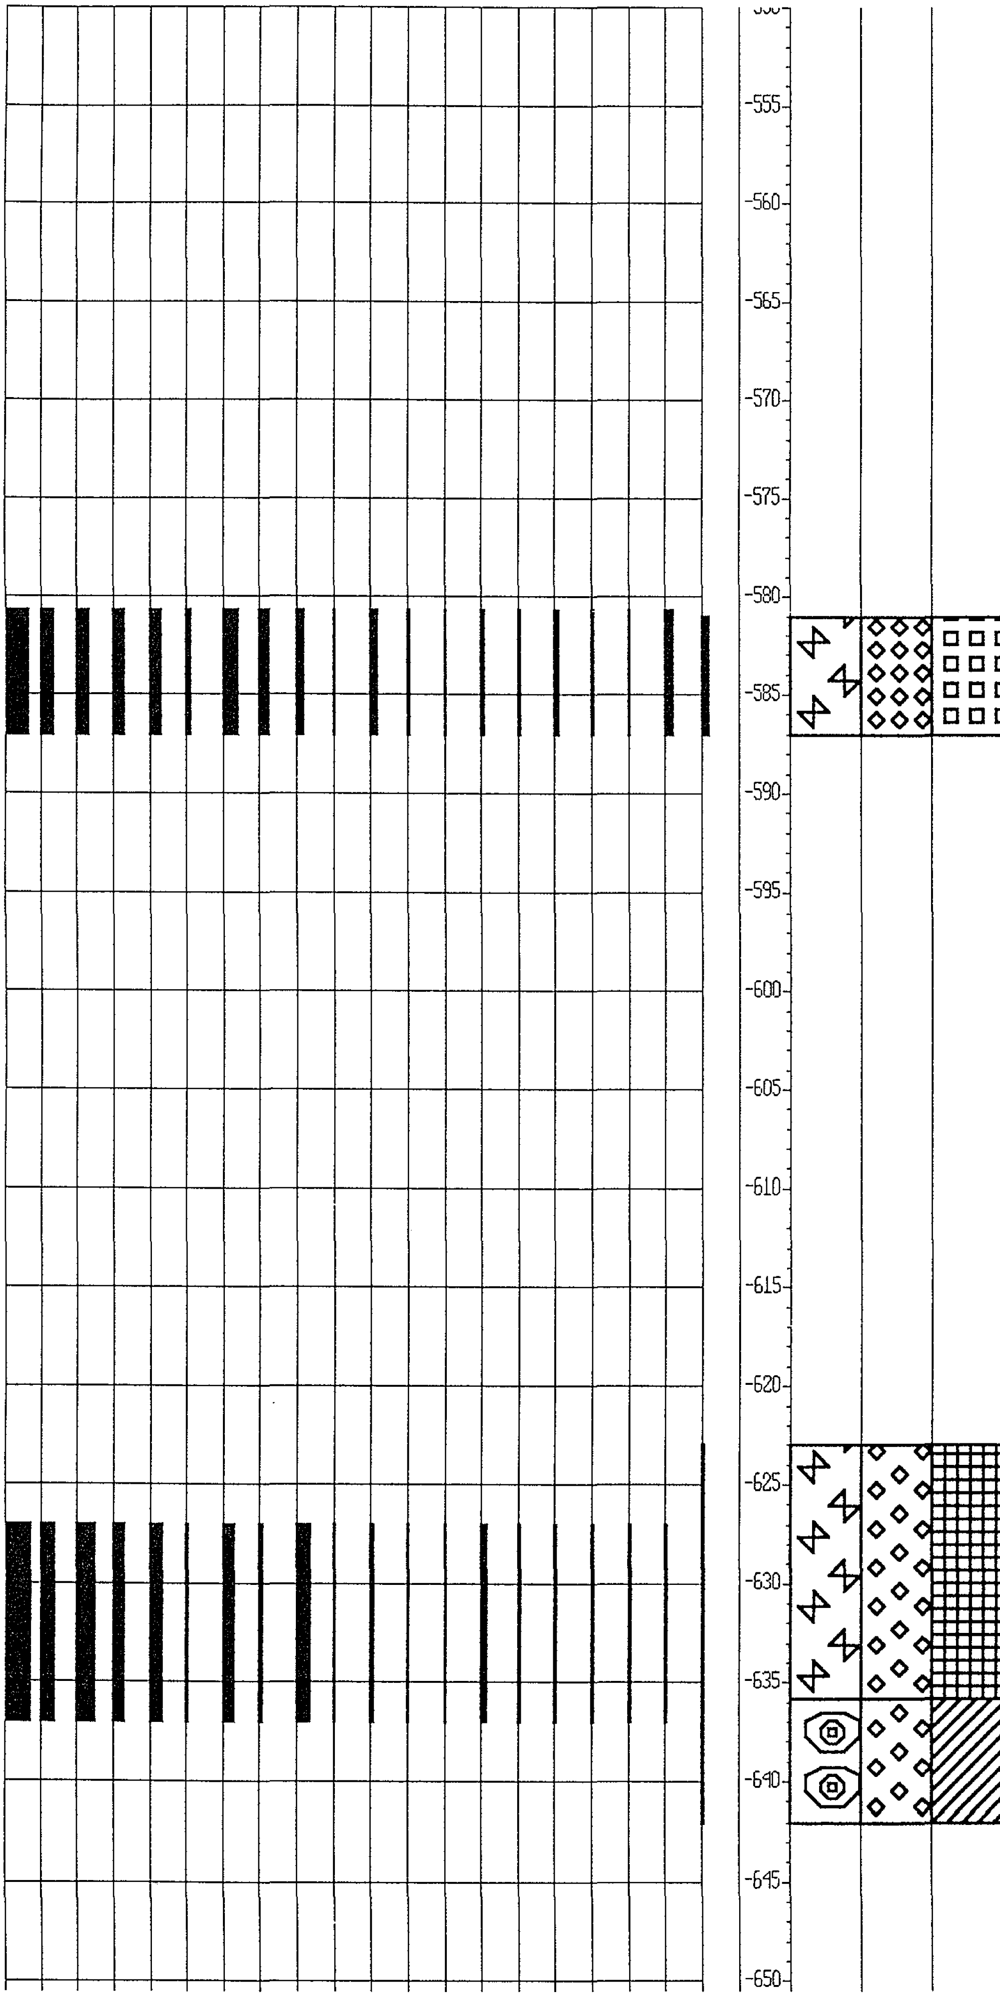
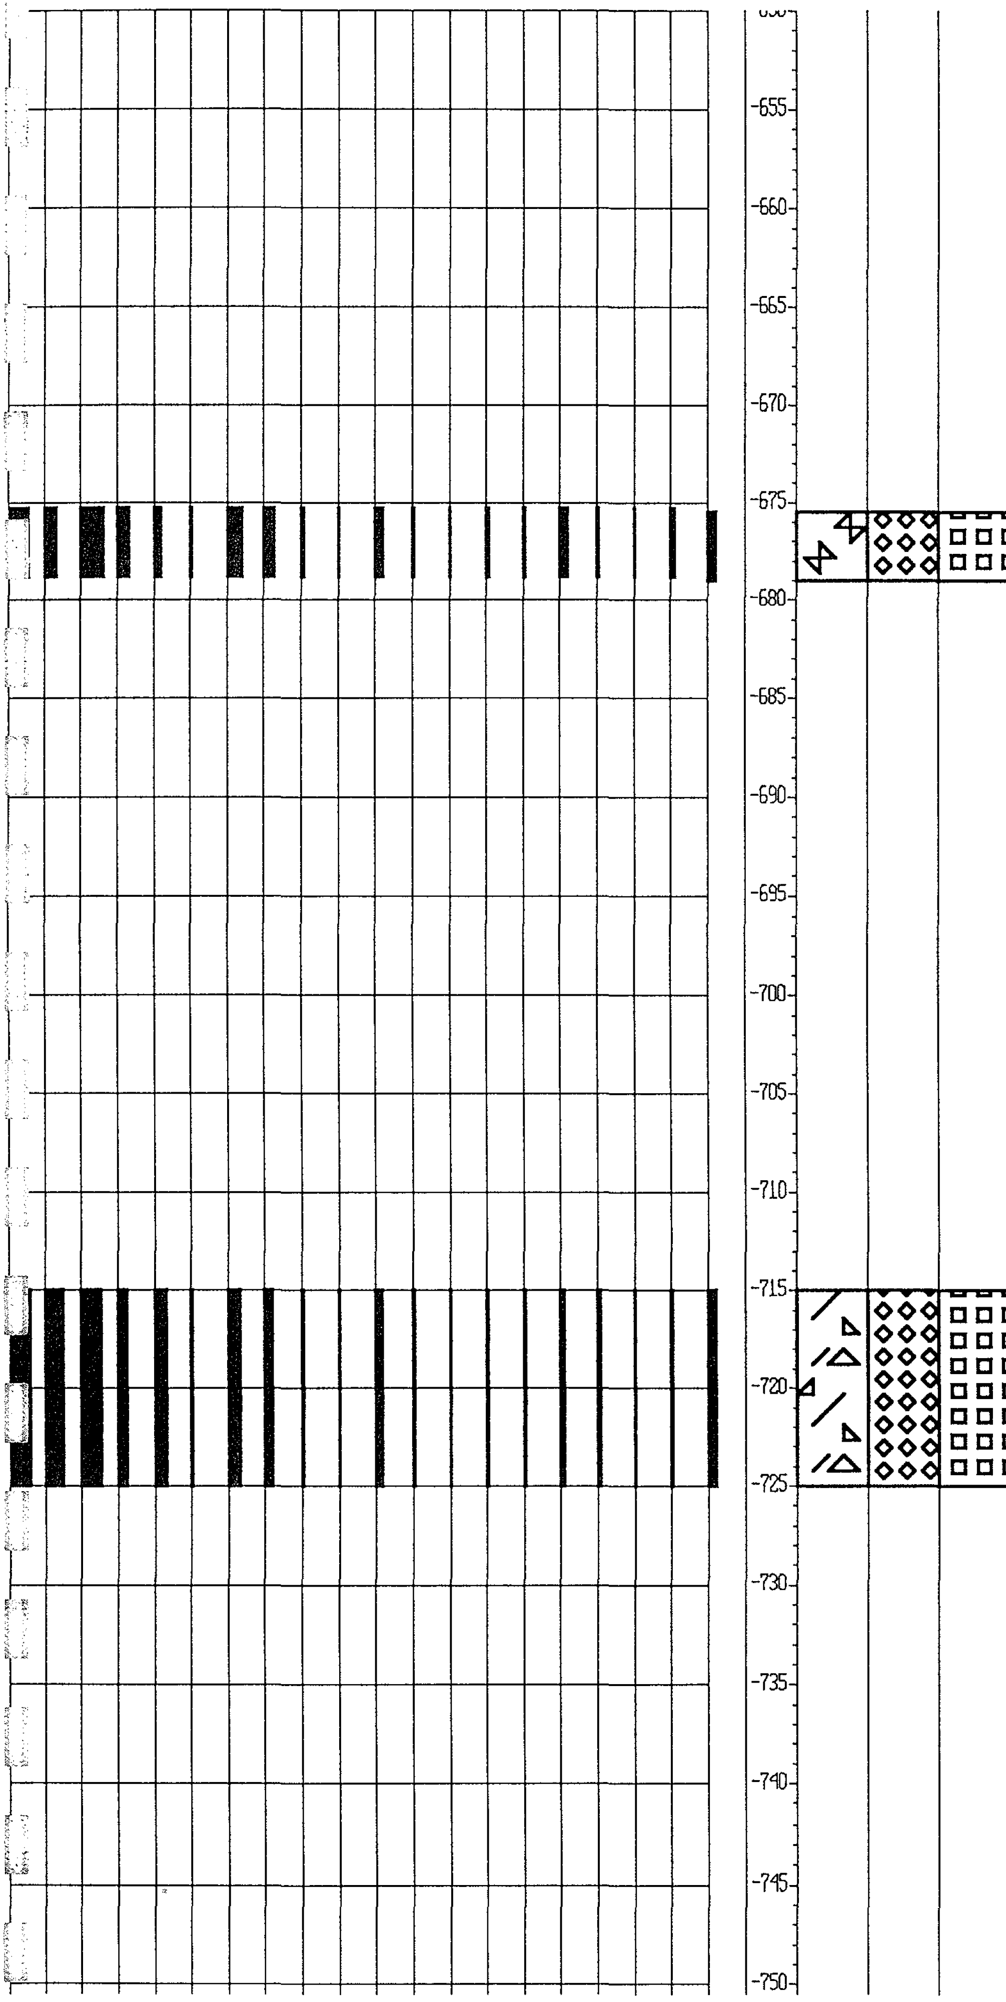
Dk-grey to black, cgr-pegmtdl-ox-rich, cu-sul-b, uralitized ol-gabb. Minor veins of vug-qtz-plag-bio-amph Monzonite. Suls of cp=po as irregular grains assoc. w/ox rich zones and large un-uralitized pyxs.



Dk-grey, cgr, oxide-rich, cu-sul-b, ol-Gabb. Same as (515.5-527').

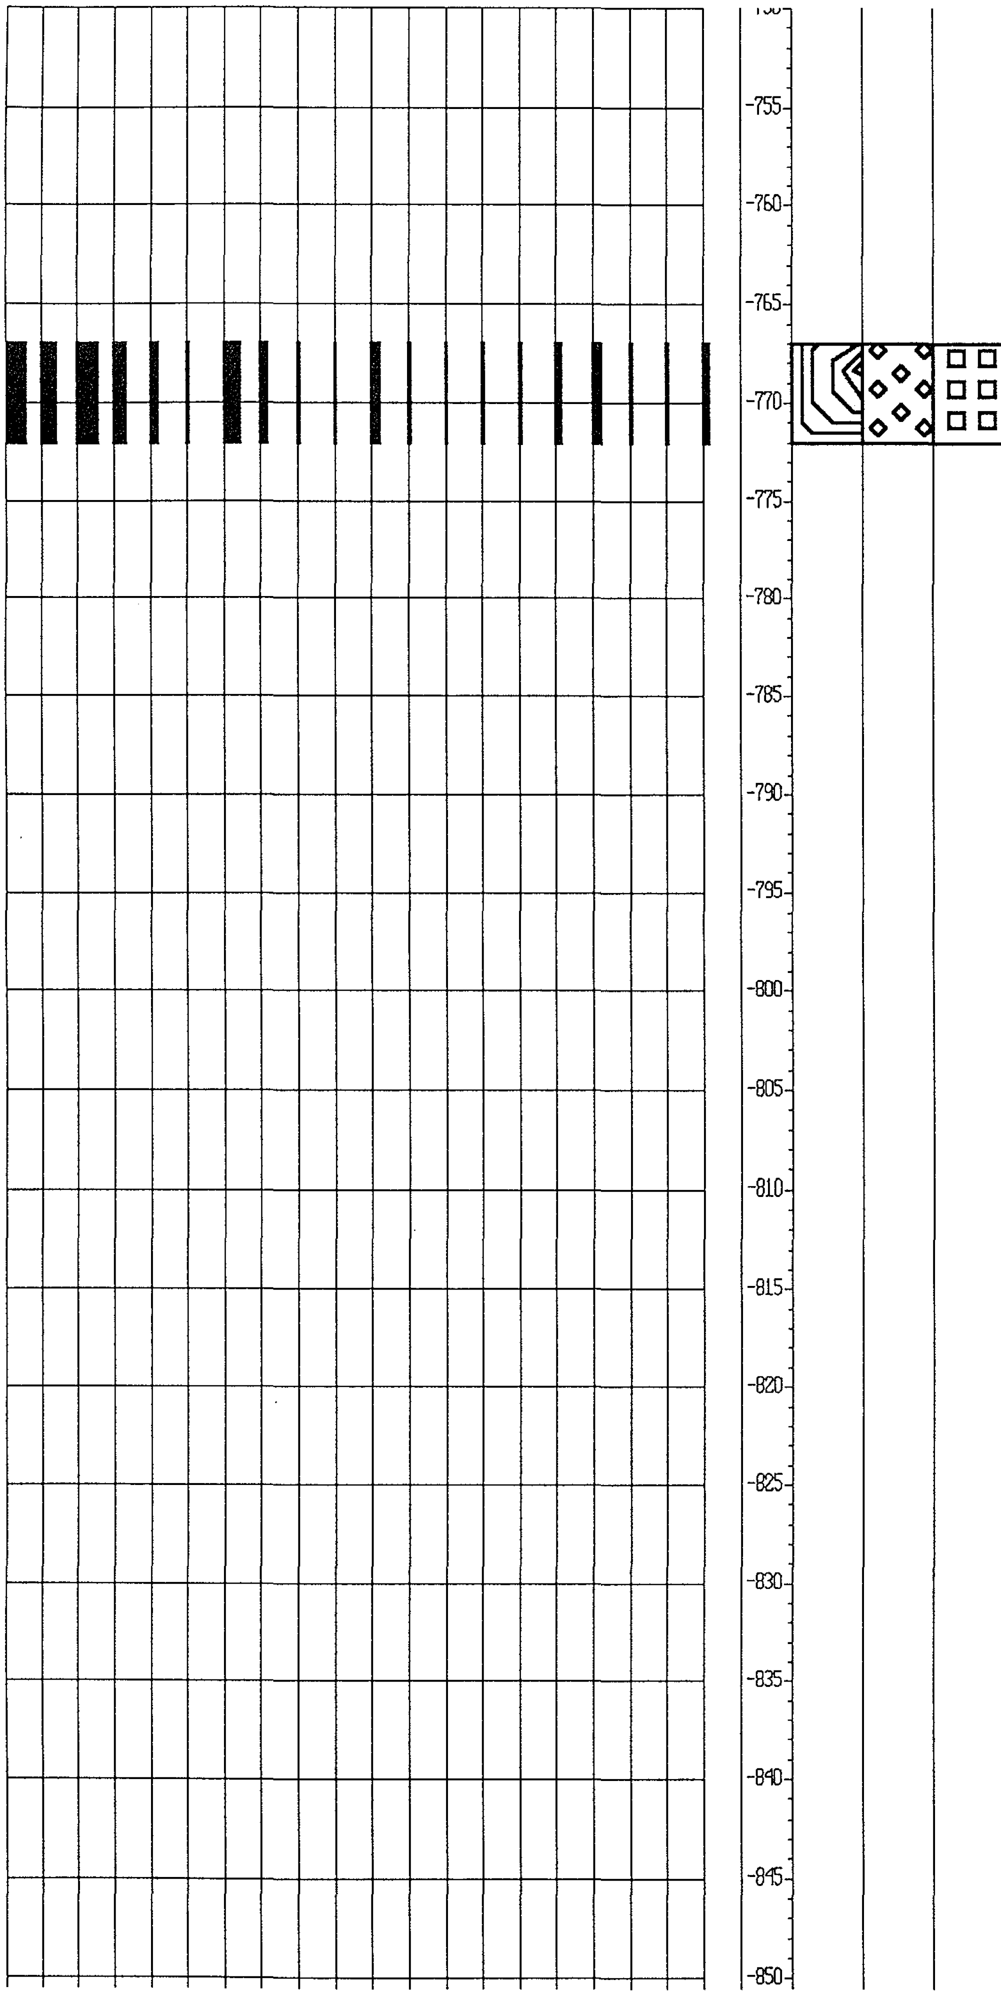
Grn-grey, cgr, bio-qtz-plag-hbl monzonite. Section is highly altered w/ bleached plagioclase and uralitized pyxs and hbl grns Gabb. Possibly a highly altered Gabb.

Grey, mgr-cgr, ox-rich, cu-sul-b, ol-b-Gabb. Suls of po>cp assoc. w/ox-rich zones. Oxs of both mgt and ilm. Alteration minor to nil.



Cgr, ox-rich gab and mgr troct. Suls occur in Gabbr as dissem grns and large irregular grns. Cp>po. Oxides of mgt & ilm occur as 1-2mm blebs and also as very large skeletal xls.

Very inhomog mixture of cgr-Troct; fgr-mgr ox-rich norite (?); and cgr to pegmtdl ox and sul-rich Gabb. Suls have a noticeable assoc. w/ ox-rich zones. Suls occur as irregular interstitial grns of cp>po.



Dark-grey, cgr to pegmtdl oxide-rich, ol Gabb. Suls of cp=po occur along pyx cleavage planes and as interstitial grns assoc w/ ox-rich zones.

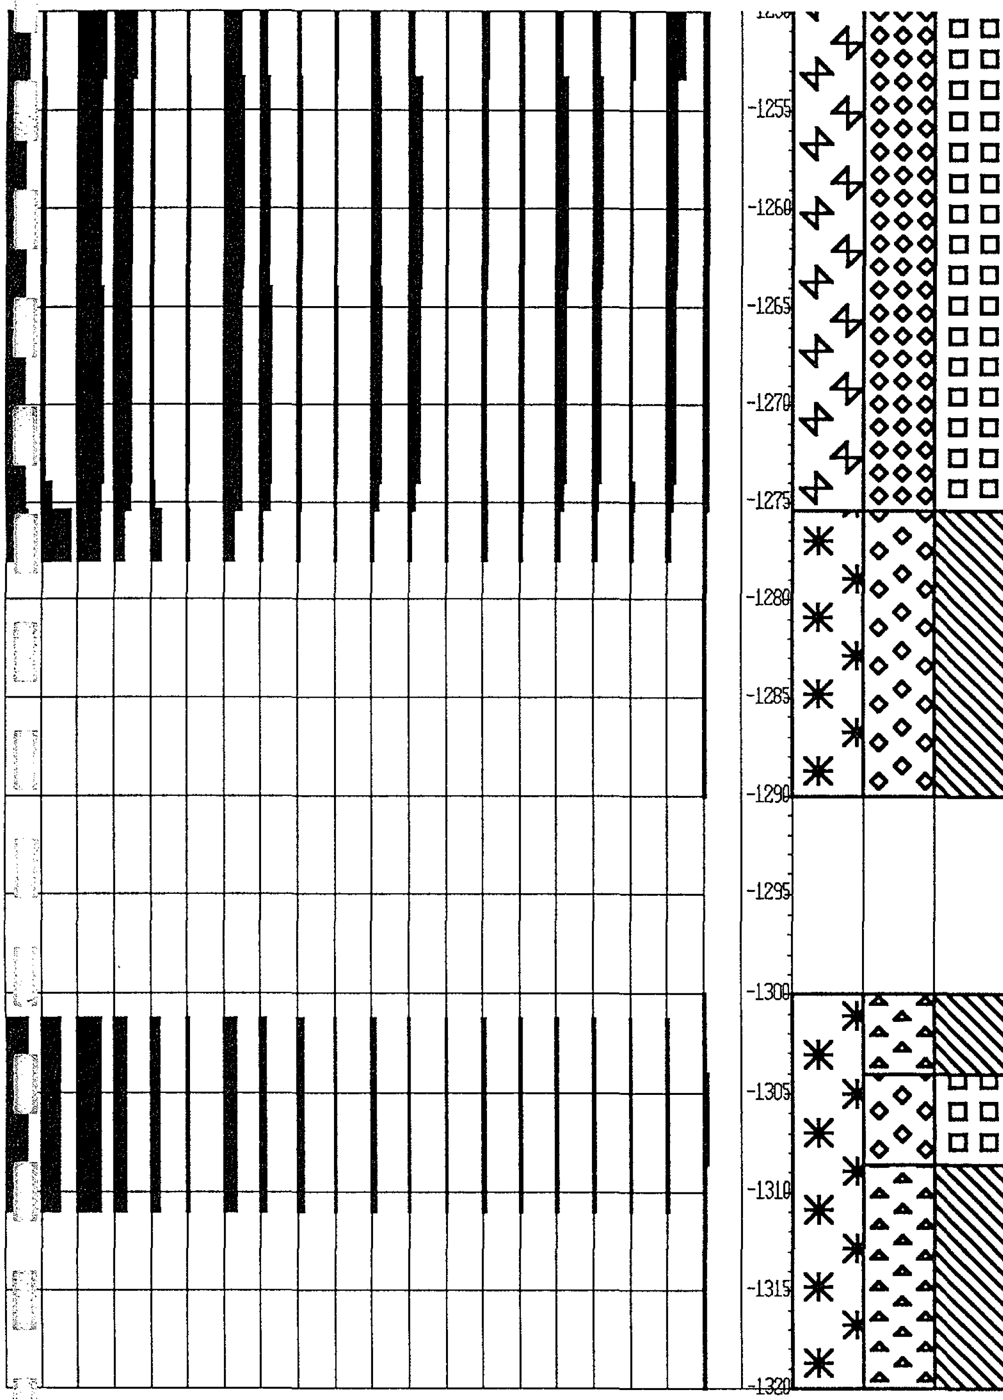
Dark-grn-black, mgr-cgr, feldspathic Pyxt to ol-pyxt. Section cut by a few thick feldspathic veins. Rock quite rich in suls and oxs. Suls of cp=po and occur as irregular interstitial grns. Oxs of both ilm and mgt.

Grn-black, serpent ultra mafic. Very thin 1-2mm. Mgt lenses follow foliation locly. From 1237.5 to 1242 the core is highly fractured and broken into small pieces.

Black, mgr to cgr, Pyxt to ol Pyxt. Whole section quite rich in cu-suls-(2-4%) and locly oxs-rich. Suls of cp=po o occur as very irregular interstitial grns. Oxs of both ilm and mgt.



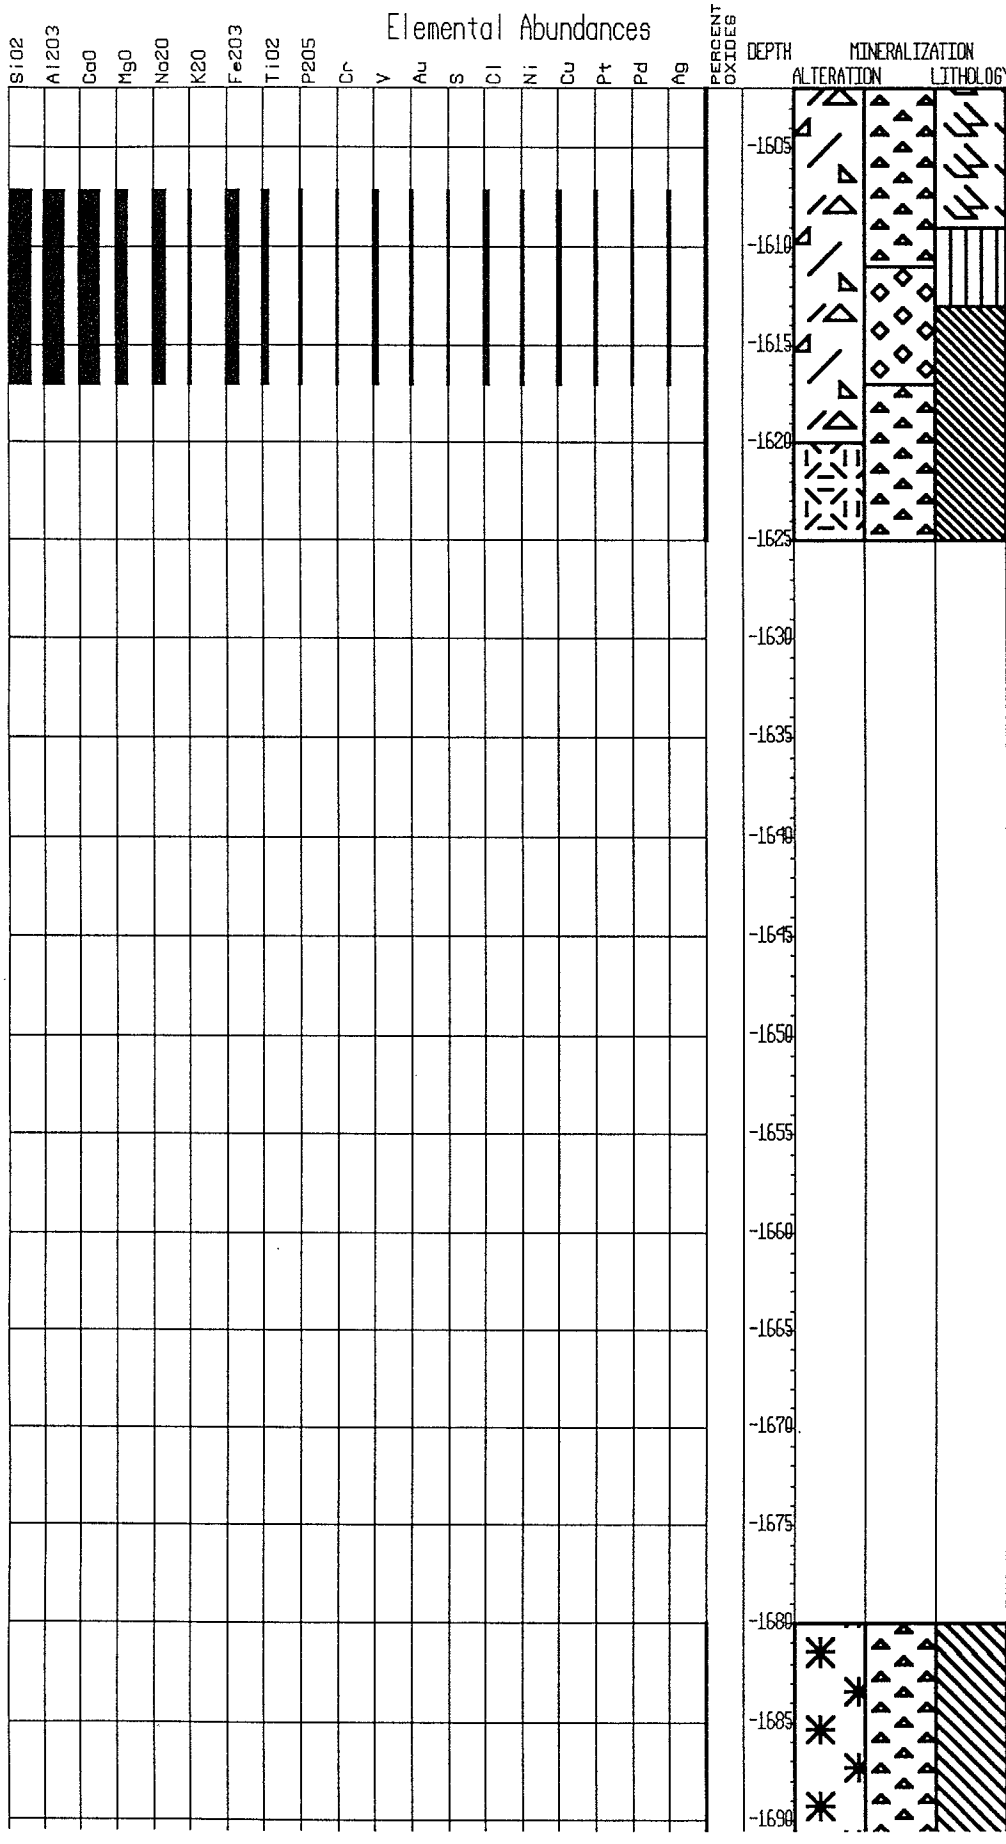
Lt-grey, cgr, homog Troct. Contact very sharp w/ Pyxt above. Section has 1-2% suls of cp as dissem grs and small 1-3mm interstitial grns.

Grey, mottled, cgr Troct no suls. Unit has up to 5% pyx.

Dark grey, cgr, cu-sul-b, ox-rich, ol mela Gabb.Pyxs occur as large oiks up to 4cm. Suls of po>cp and occur as 1-4mm interstitial grns.

Grey, mottled, cgr, Troct suls not noted at all. The unit has 1-5% pyx.

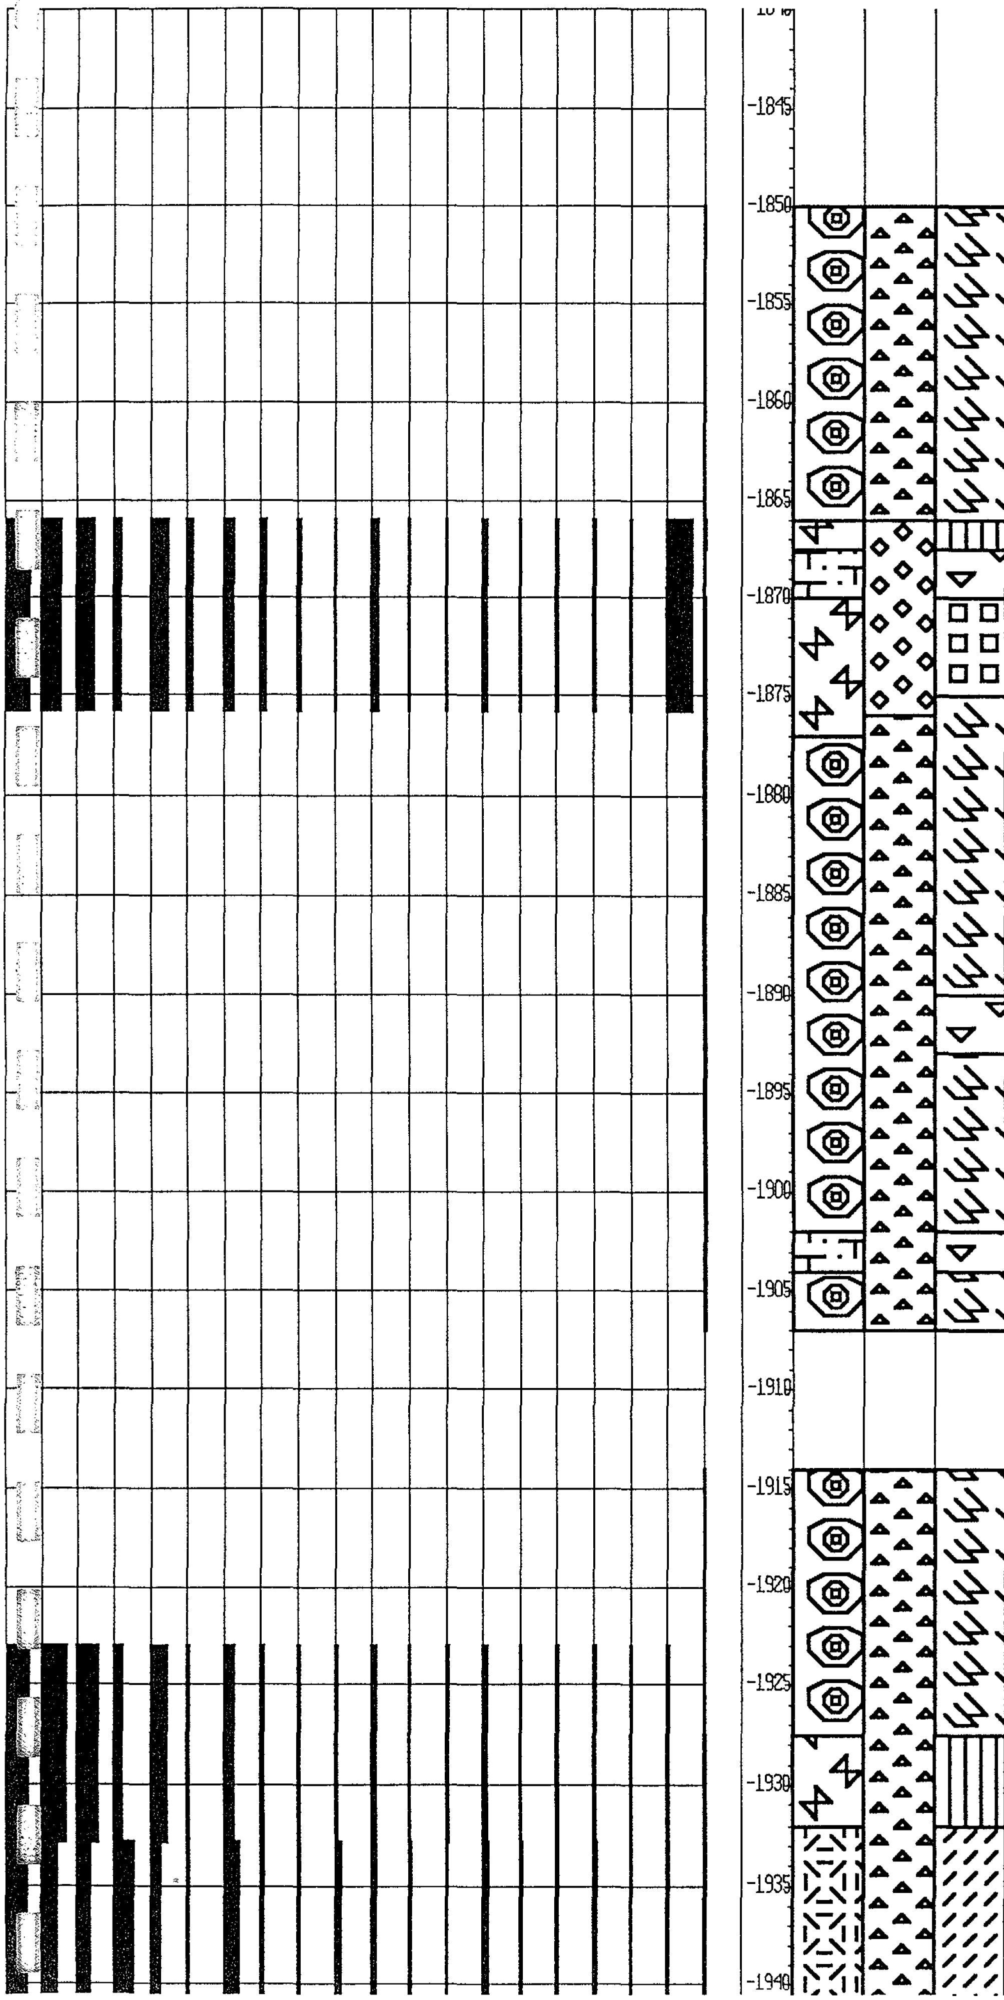
DDH BA-4 PART 2



DESCRIPTIONS/COMMENTS

Mixed zone with cgr-anortc-Troct. and, fgr-mgr, ox-rich cu-sul-b, Norite, and minor cgr, ox-rich, ol-Gabb. Minor serpentn at 1620-1624.'

Lt-grey, cgr, Troct. Ox-rich and cu-sul-b mgr-pegmtdl at (1690-1692', 1715.5-1722', 1740-1747', 1797', 1799-1804', and 1810'.5-1812'). Minor biot-granite veins locally assoc w/ox-rich zones. Up to 2% suls in ox-rich zones.



Lt-grey, cgr, trocc-Anorth to anortc-ol-Gabb. Section cut by many pegmtdl-bio-Granite veins w/ uralitization common around Granites. Unit locally ox-rich and cu-sul-b. Gabb assoc w/ the granites. Suls of cp=po up to 2% in ox-rich portions.

Lt-grey, cgr to pegmtdl, anortc-ol-Gabb. Locly has large 3-4cm skeletel ilm grns.

Dk-grey, cgr, ol-Gabb. Locally moderately serpent. Moderate uralitization of pyxs (2-5% oxs of ilm and mgt).

Dark-grn, mgr, serpent pyx-Troct or pyx-Picrt. Original composition difficult to determine due to moderately-high serpentn. Rusty red drops on core from 1940-1947.

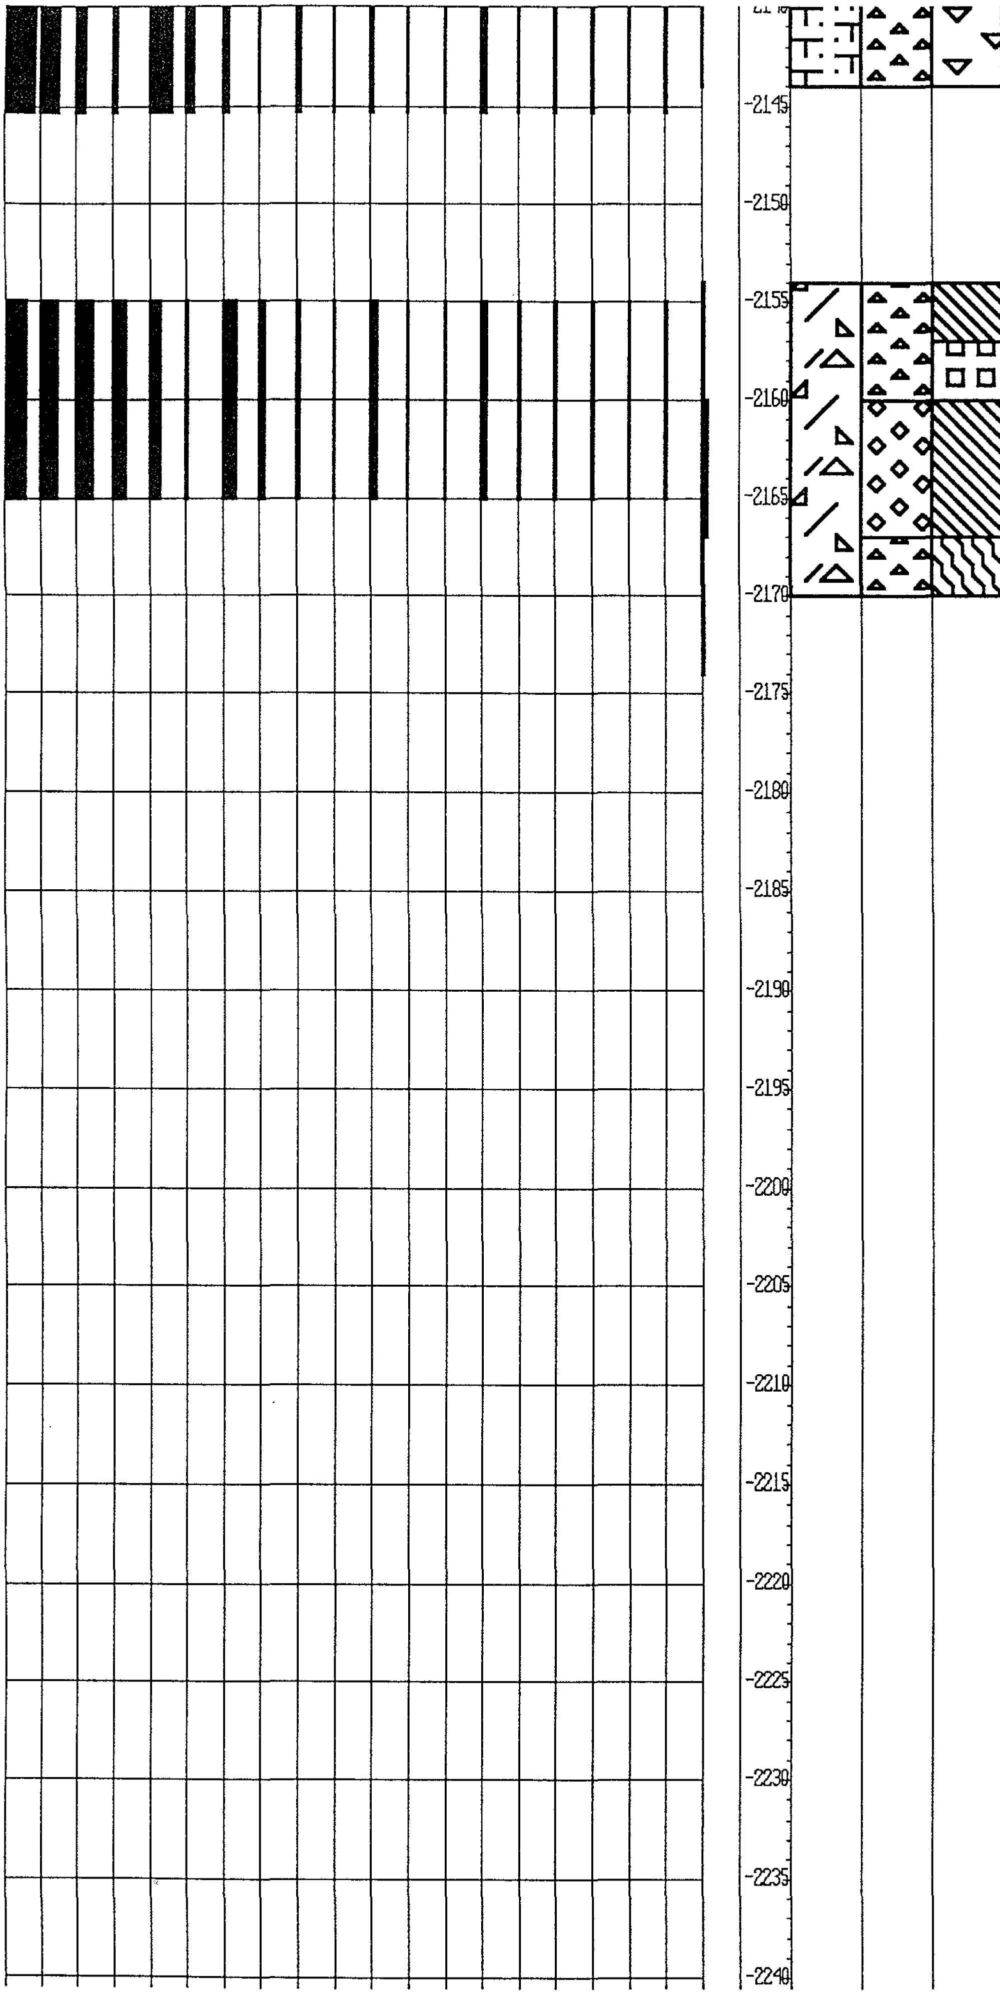
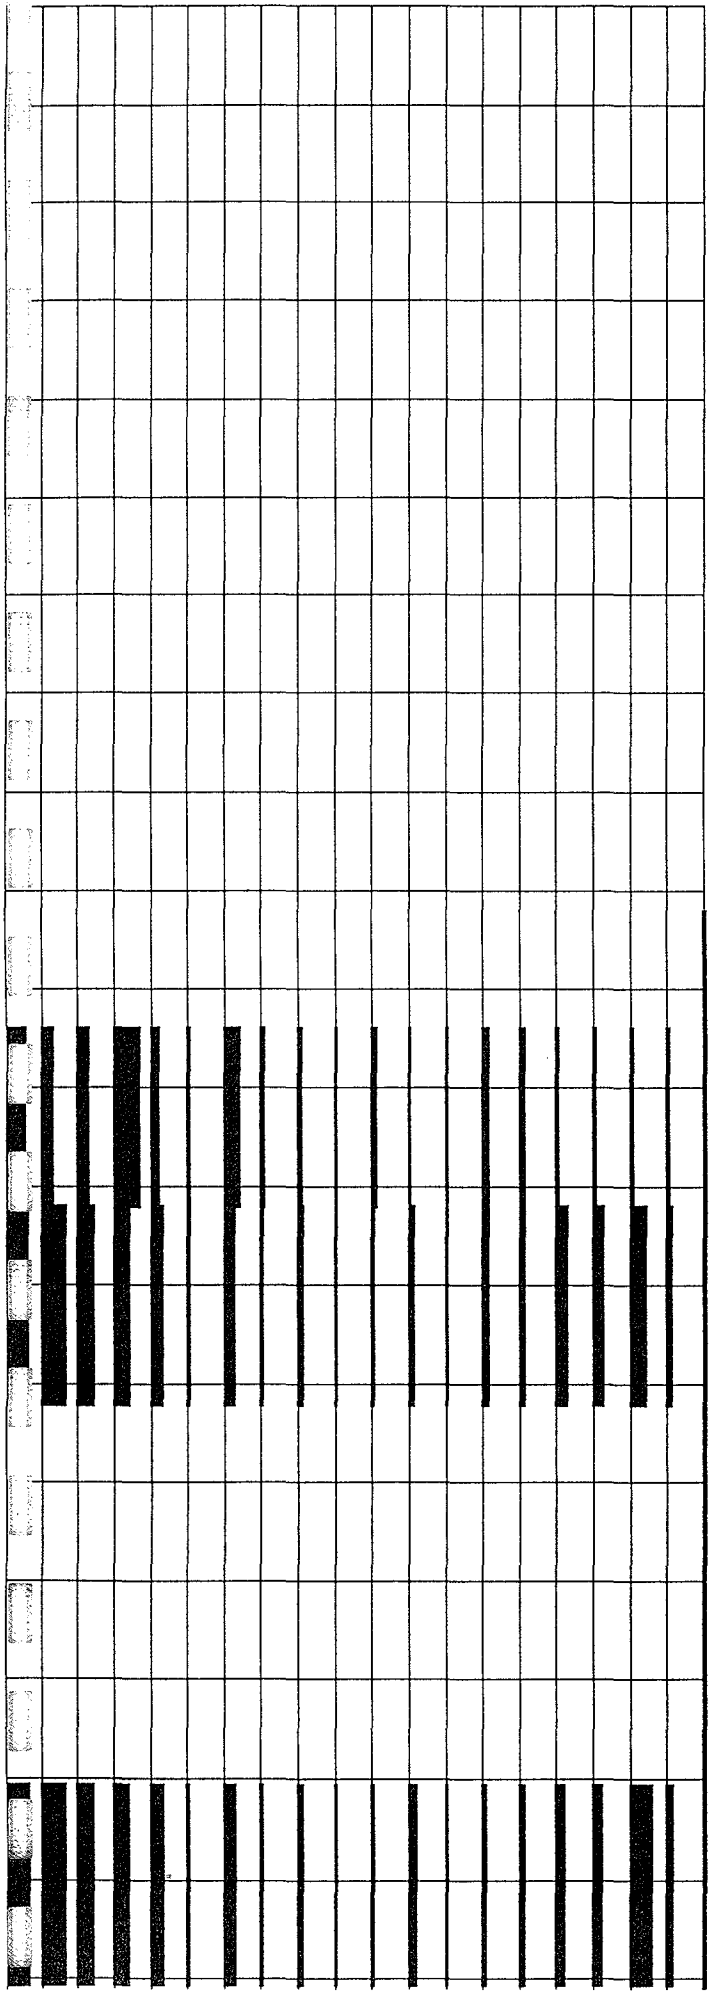
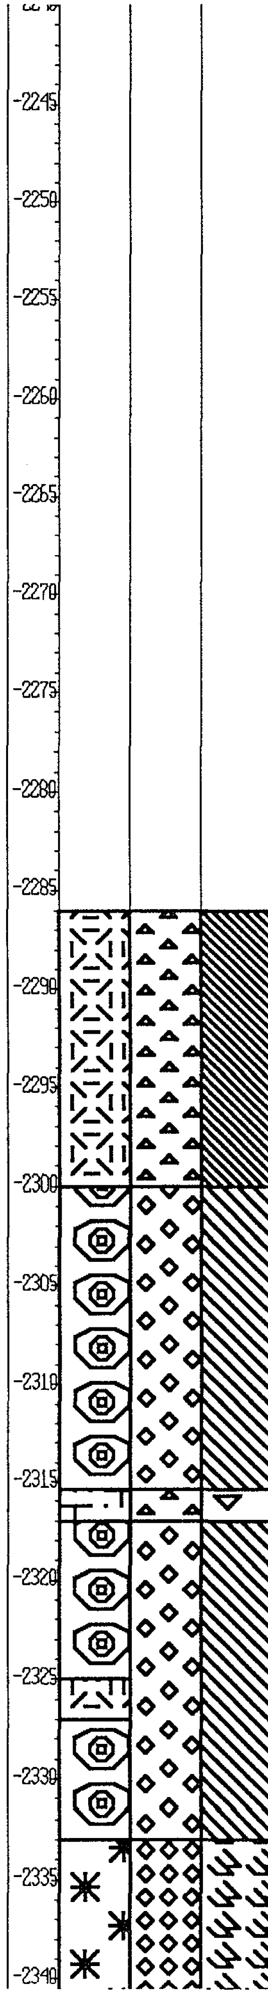
White, pegmtdl, biot-plag-Granite or Tonalite. Qtz present as myrme-kitic intergrowths in feldspar. Moderate alteration of bio to chlorite. Upper ctc sharp but lwr. ctc. gradational.



Mixed zone of cgr Troct. and cgr, ox-rich, cu-sul-b, ol-b-mela-Gabb. Section very inhomog. oxs of mostly mgt up to 15% in mela-Gabb. Suls of po>cp as dissem grns.

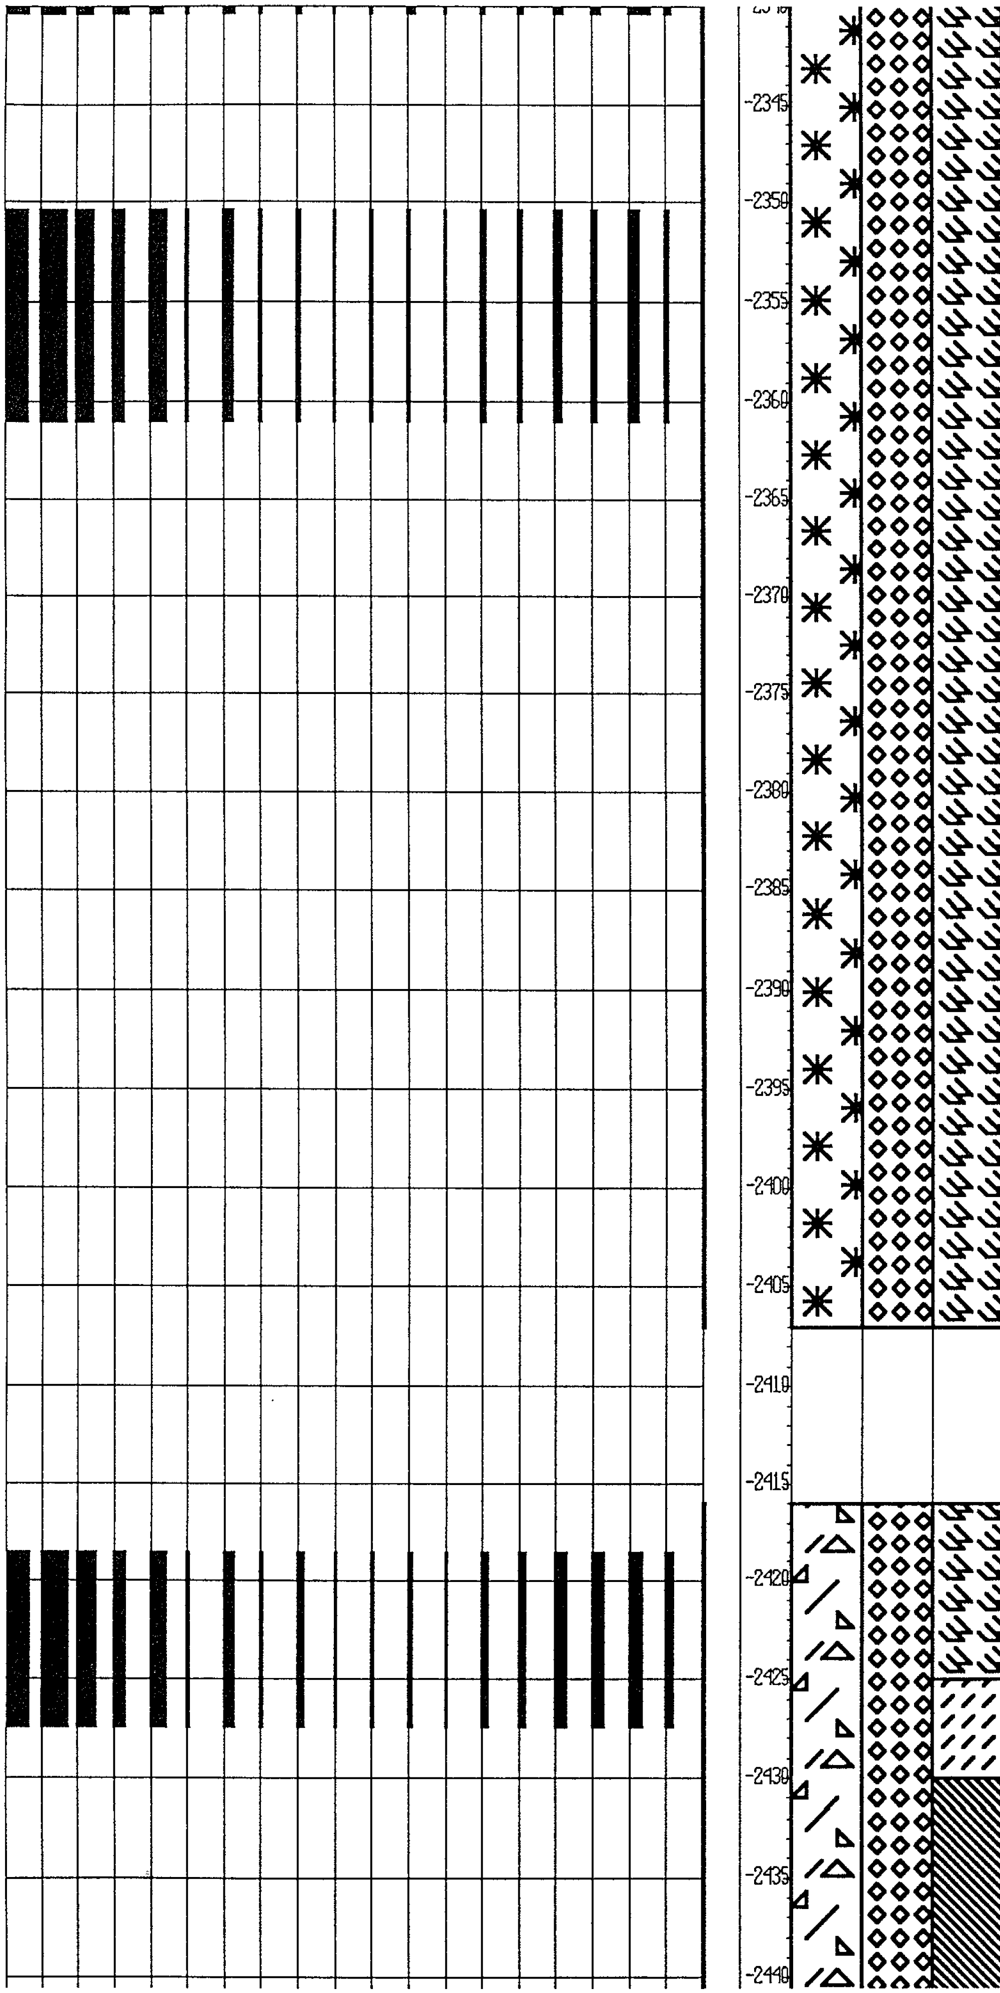




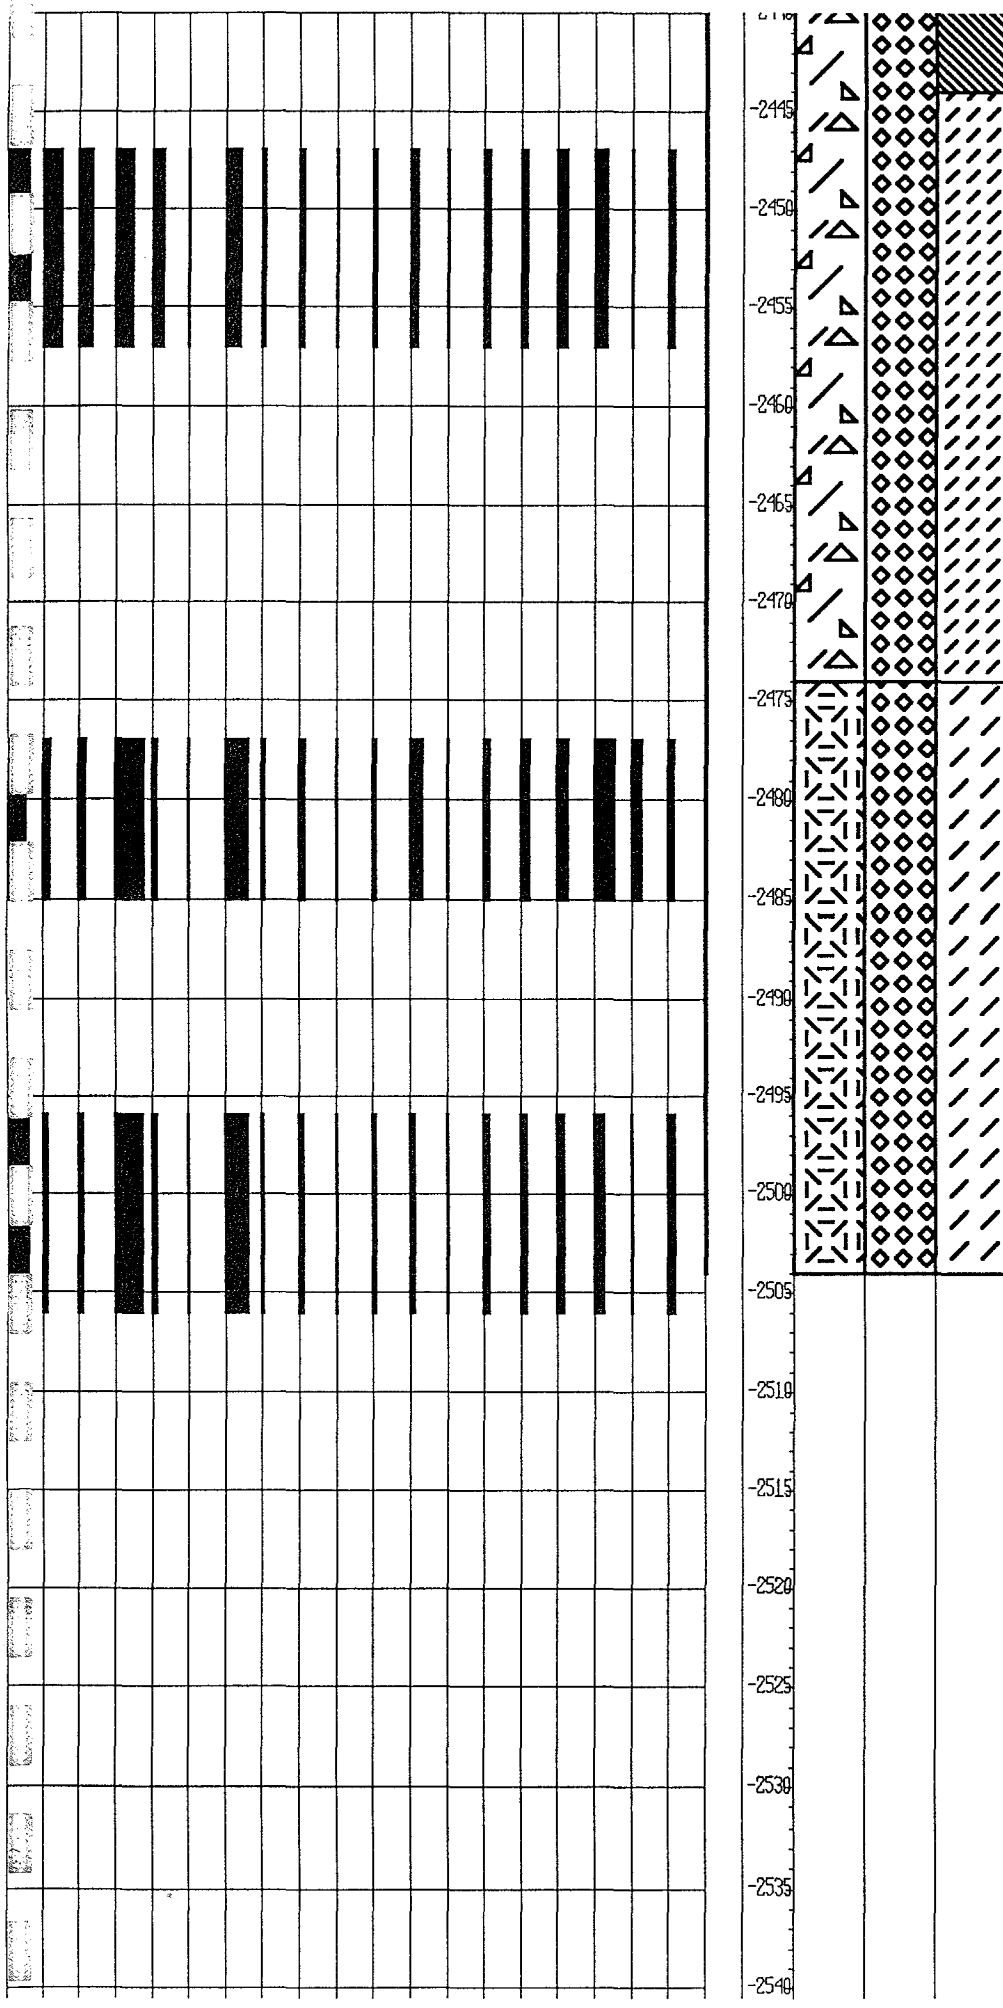
Dark-grn, cgr, serpent. pyx-Troct. Rounded plag xls through-out (10-15%) . Pyx oiks easily visible. Suls not noted at all. Protolith difficult to determine due to serpentn.

Grey, mgr, cu-sul-b, troct. Suls throughout as dissem grns of cp and minor po. Unit cut by a 2' granite vein at 2316'.

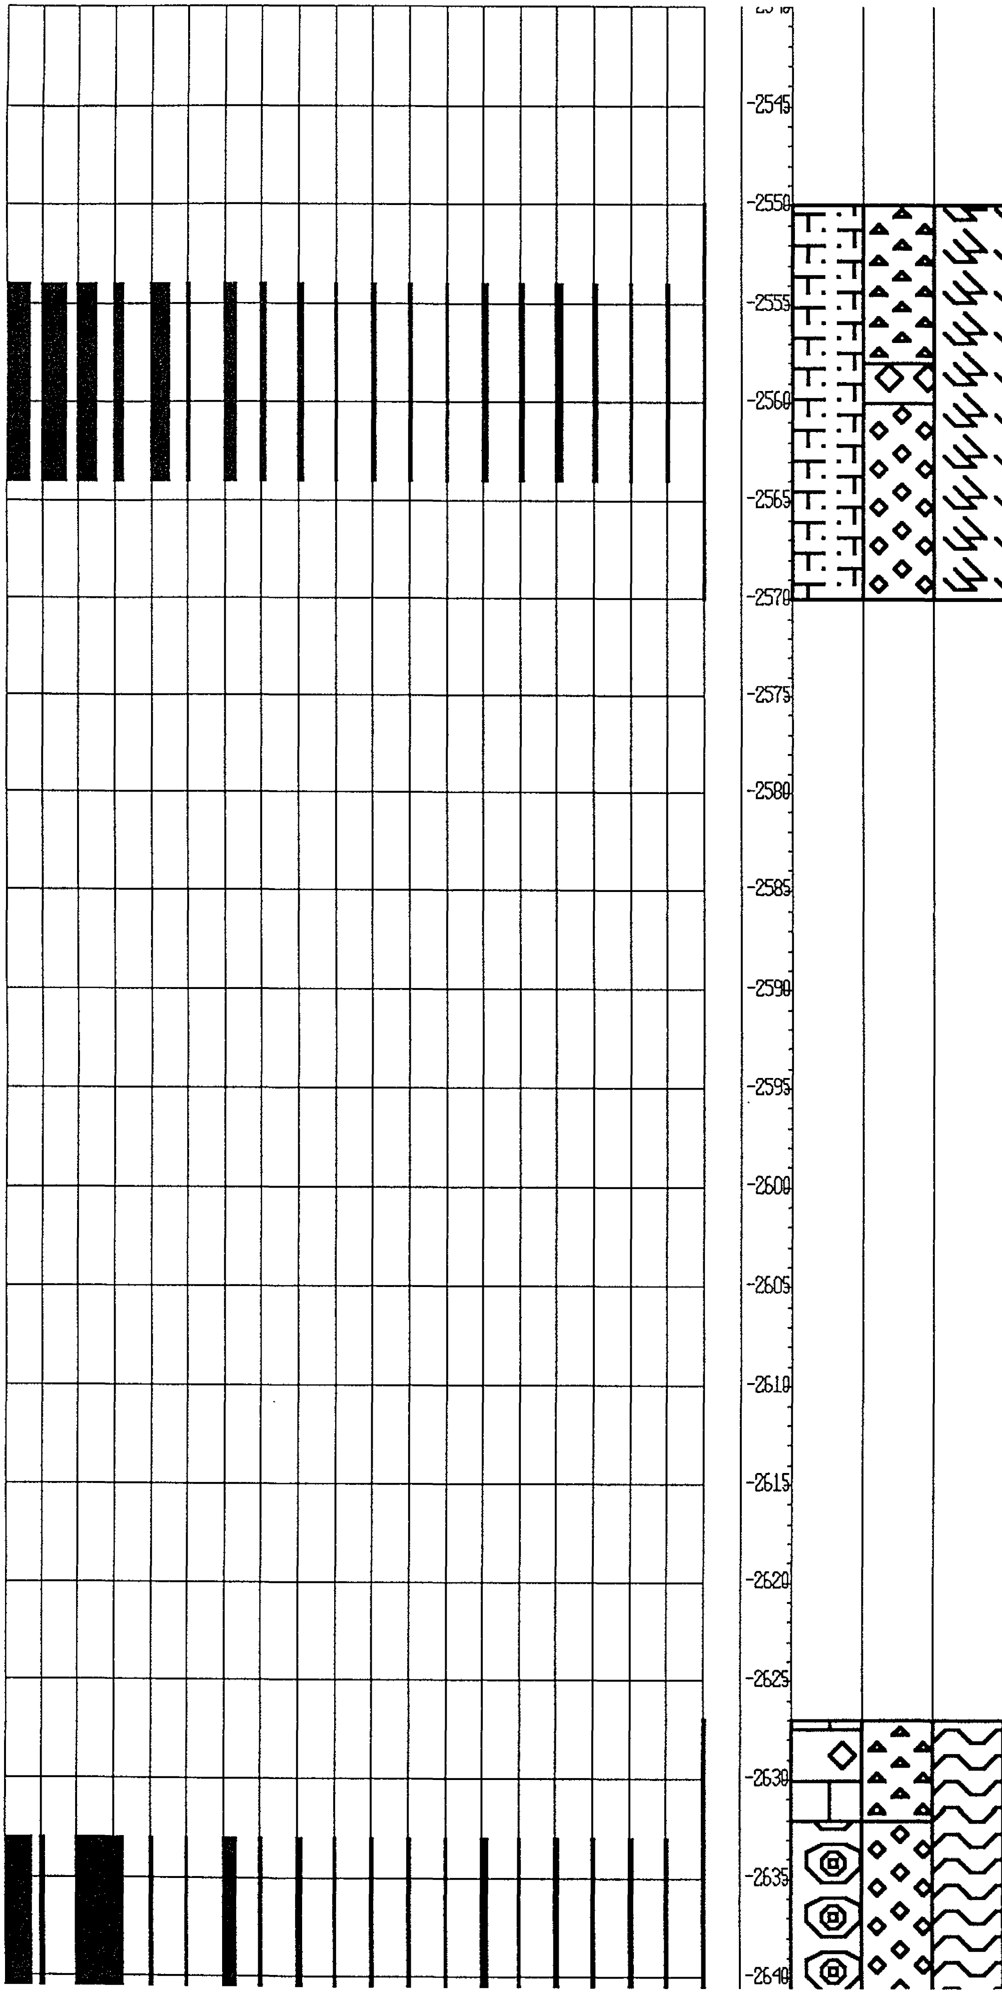
Grey, cgr, cu-sul-b, pyx-b, anortc-Troct, section very homog. Pyx occurs as widely spaced grns of cpx suls throughout, (1-3%) as dissem grns and local cgr blebs of cp>po. Bio assoc w/ cgr blebs of sul.



Grey, mgr-cgr, mixed, cu-sul-b anortc-Troct and mgr, cu-sul-b Picrite. Pyx grns scattered throughout as large subophitic grains. Suls occur as dissem grns, (cp>po), and as large ireg blebs assoc w/ pyx grains. Minor suls along fractures.



Black, mgr, cu-sul-b, ox-b, Modly-serpent, Picrt. Dissemd cp and po throughout avg 3-4%. Rusty-red drops on core at 2472-2496.5. Gradational ctc w/ unit above and sharp ctc w/biot-Granite below.



Grey, cgr-pegmtdl, cu-sul-b, trocc-Anorth. Suls of cp and po as ireg grns and large blebs up to 10mm. Sul content ranges from 0-7% over 12in intervals.

Thinly-bedded, thermally metamorphosed Iron Formation. Upp 5' a calcite marble. cu-sulfides occur, in underlying calc-silicate rock from 2632-2644' as interstitial grns of cp between subhedral grns of diopside. Rock very well layered from 2649' on down.
