\text { pandemic. }\end{array} \\
\hline & \begin{array}{l}\text { Bear Management Units }\end{array}
$$ <br>
Fig. 2 There are currently 14 Bear Management Units (BMUs) where license sales are <br>
limited by a quota, 1 BMU where the number of permits is unlimited, and 4 BMUs with <br>
no quota at all. The BMU divisions in the no-quota zone are for internal data analysis <br>
purposes only: hunters do not have to choose a BMU in which to hunt within this <br>
zone. In the quota zone, hunters must apply for a certain BMU and are drawn through <br>
a preference lottery based on their number of previously unsuccessful applications <br>
(Table 4). The first digit in each BMU (1-5) refers to 5 larger BMUs in which each was <br>
previously a part (when numbering began in 1985). Since then, several BMUs have <br>
been split, to better adjust hunting pressure. In 2016, BMU 26 was divided into 27 <br>
and 28, and BMU 44 was split into 46 and 47 (BMUs 28 and 47 comprise the Leech <br>

Lake Reservation). This split, along former BMU lines, allows current data to be\end{array}\right\}\)| regrouped into these former BMUs and thereby compared to older data (which is |
| :--- |
| done in this report). In 2022, BMU 14 was split from BMU 12. BMU 451 was split from |
| BMU 45 in 2020 as an experimental unit to understand if we could reduce crop |
| damage through hunting. The results for this BMU are reported under the quota zone |
| but were not remerged with BMU 45. This is because of the unlimited number of tags |
| in BMU 451, so BMU-level results would not be comparable with previous years. |$|$

| Table 4 | Resident vs. Non-resident hunters <br> The proportion of resident hunters has remained stable for the past 5 years. The Northwest no-quota zone (BMU 11) consistently had the highest proportions of nonresident hunters ( $17 \%-29 \%$ ). |
| :---: | :---: |
| Table 5 | Quota zone lottery <br> We do not have (nor have we ever had) a bear population that can sustain levels of harvest where everyone who applies for a tag is successfully drawn. The low quota zone permit availability over the past 11 years has made it increasingly difficult to succeed in the lottery, and thus wait times remained high in some areas in 2023. The trade-off is that the quality of the hunt and the success rates are exceedingly high in the quota zone (Table 1, Fig. 1). First-time and second-time applicants were successful only in BMU 22 (wilderness area hunt). Four BMUs required a preference level of 4 for guaranteed success, and BMUs 24, 27, 28, 45, 46, and 47 required a preference level of 5 or above for any chance of drawing a tag. This high threshold for these BMUs is due to the increasing number of applicants this year (Fig. 3), not a reduced number of available permits (Table 2). |
| Table 6 | Harvest by BMU <br> The statewide harvest in 2023 was $20 \%$ lower than 2022, and $39 \%$ lower than 2021. This was likely due to the range-wide boom in production of natural bear foods for the second year in a row, coupled with a very warm opening weekend. The sex ratio of the harvest was $\geq 60 \%$ males in all BMUs, except 22 (BWCA). The statewide harvest sex ratio has exceeded 60\% male in all years except 2021 and 2020 since 2013 (Table 1) when permits were reduced. However, these same highly male-biased sex ratios have also occurred in the no-quota area, suggesting that it is not just due to low hunter density. When natural foods are poor, reproductive females are far more likely to be shot than in average or good food years. |
| Fig. 4 | Harvest by quota vs no-quota zones <br> Permit availability continuously declined during the decade 2003-2013 (Table 1), and commensurately, total harvests declined and the percent of the harvest in the noquota zone increased. The percent harvest in the no-quota zone was down this year slightly, split evenly between BMUs 11 and 52 (Table 5), as was the proportion of hunters in the no-quota. Participation of no-quota hunters has declined the last two years from the record high in 2021 (Table 1). |
| Table 7 | Hunting success by BMU <br> In 2023, success was at or below the 5 -year average in quota zones in all BMUs. Many were below the 5 -year average due to abundant natural foods and high temperatures during opening weekend. The success rate in the quota zone was nearly 3 times higher than in the no-quota zone ( $33 \%$ vs. $12 \%$, respectively). Success rates in the no-quota were below long-term averages (notably low harvest in BMU 52). |
| Table 8 | Harvest by date |

|  | During years of normal fall food abundance, about 70\% of the harvest occurs during the $1^{\text {st }}$ week of the bear season, and about $83 \%$ occurs by the end of the $2^{\text {nd }}$ week. This year lagged behind this pattern somewhat, due to the abundant crops of natural foods across Minnesota this fall and high temperatures during opening weekend. |
| :---: | :---: |
| Table 9 \& Fig. 5 | Human bear conflicts <br> The total number of recorded bear complaints has been stable for a decade but has fluctuated with natural food abundance. A new recording system was instituted in 2017 whereby Wildlife Managers recorded all bear complaints online as they were received, instead of submitting reports at the end of each month (thus, unlike previous years, Managers who had no complaints were not counted in the number of personnel participating). Conservation Officers implemented a similar system beginning July 2019. This dramatically increased the reporting rate of Conservation Officers. This year, we received the fewest number of bear complaints since we started recording these data in 1980. |
| $\begin{gathered} \text { Tables } 10- \\ 12 \\ \text { \& Fig. } 6 \end{gathered}$ | Food abundance <br> The composite range-wide, all-season abundance of natural bear foods (fruits and nuts) in 2023 was the $4^{\text {th }}$ best on record. Abundance of many summer foods was above the long-term (38-year) average for all regions. In general, summer food conditions were exceptionally good across the state. The statewide fall food index (productivity of dogwood + oak + hazel), which helps predict annual harvest after accounting for hunter effort (Fig. 11), was the $3^{\text {rd }}$ best year on record. Hazelnuts, acorns, and dogwood berries were above average in many areas of the state. The oak production this year was exceptional in almost all areas where oaks exist. |
| Fig. 7 | Predictions of harvest from food abundance <br> The 2023 statewide harvest was roughly what was expected, based on regression of harvest as a function of hunter numbers and the fall food productivity index. For the quota zone, the actual harvest in 2023 was nearly the same as predicted by this regression. |
| Figs. 8-9 | Submission of bear teeth for aging <br> Ages of harvested bears are used as the principal means of monitoring population trends. Although hunters are required to submit a tooth from their harvested bear, historically $\mathbf{>} 25 \%$ did not comply. Reminder notices were sent to non-compliant hunters each year during 2014-2017, which spurred a higher initial compliance the following years ( $>80 \%$ ). Since 2018, with no reminder mailing, compliance has been $82-87 \%$. Since 2013, hunters could register by phone or internet, and pick up a tooth submission envelope later: tooth submission compliance by these hunters has equalized across all registration types. A decreasing proportion of hunters are registering their bear at a registration station over the past years. Compliance with tooth submission was higher in the quota zones than in the no-quota area but was especially low ( $<80 \%$ ) in a number of units (BMUs 10, 12, 22, 41, and 52). |

| Fig. 10 | Population trend: Statewide and quota vs no-quota zones <br> A new Bayesian model developed by Allen et al. (2018) for bear monitoring in <br> Wisconsin includes not only the sex-age composition of harvested bears (like the <br> Downing), but also reproductive and survival parameters (obtained from data <br> collected from long-term monitoring of radio-collared bears in different study sites <br> across Minnesota). The trajectory of this model is robust to assumption violations but <br> seems to be an underestimate compared to our tetracycline estimates. The models <br> for this year indicated that the statewide population has stabilized and is slowly <br> recovering. It is also not dissimilar to the Downing model overall trajectory. Notably, <br> the quota area as a whole has stabilized since 2012 and has been increasing steadily <br> the past couple years. The no-quota area has been increasing steadily for the last 20 <br> years. |
| :---: | :--- |
| Trends in harvest rates |  |
| Fig. 11 | The sex ratio of harvested bears varies by age. Male bears are more vulnerable to <br> harvest than females, so males always predominate among harvested 1-year-olds <br> (67-75\%). Males also predominate, but less strongly, among 2 and 3-year-old <br> harvested bears. However, older-aged harvested bears ( $\geq 8$ years) are nearly always <br> dominated by females, because, although old females continue to be less vulnerable <br> as individuals, there are far more of them than old males in the living population. The <br> age at which the line fitted to these proportions crosses the 50:50 sex ratio is <br> approximately the inverse of the harvest rate. Segregating the data into time blocks <br> showed harvest rates increasing from 1980-1999, then declining with reductions in <br> hunter numbers (Fig. 1). Based on this method, harvest rates in recent years have <br> been similar to the early 1980s when the population was similarly small (~15\% of the <br> total bear population was harvested). |

## Population trend: BMU-level estimates

Using the Allen et al. (2018) population model, we were able to estimate population trend for each BMU. This has been something out of reach until this year due to limitations from small annual harvests over time and the insensitivity of the Downing model with small populations. The population estimates tended to follow what we know about bear reproduction in Minnesota. The poor soils in NE Minnesota BMUs produce less bear food and subsequently, have much lower bear reproduction (BMUs $24,25,31$ ) than areas farther south. In the western and southern BMUs (the periphery of bear range in Minnesota), oak forest and agriculture provide bears with abundant food. Bears in these BMUs (11, 46 and 47 [former 44], 45, 51, and 52) reproduce at younger ages and will be the quickest to recover from the population reduction in the 2000s. The remaining BMUs have reproduction levels between the north and south. They are the areas we would expect to stabilize and recover after the periphery of bear range.

Caution in interpreting the estimates is needed. Modeled population trends are far more robust than population estimates for a given year. The scale (estimated population size) is not as accurate as the overall trend (increasing, decreasing, or stable). There is little to no population closure in any given BMU due to their small size and the frequency of bear migration in MN. Furthermore, a way to evaluate our current management goals is to compare the most recent estimates with those in 2012-2013, when permits were cut dramatically. Harvest quotas have been essentially level since that point and comparing with that cut point will allow for a better understanding of recent trends.

Fig. 12
After permit cuts in BMUs 12, 24, 25, and 31 last year and the abundant natural foods, there seems to be some flattening of the decline in BMUs 25 and 31. This is welcome news and is a good indicator that the cuts are helping. We'll need a few more years of low permit numbers in these BMUs to ensure the population has stabilized and the decline has reversed.

The good news is that populations in BMUs 26 (current BMUs 27 and 28), 41, 44 (current BMUs 46 and 47), 45 , and 51 seem to have stabilized since the permit cuts in 2012. All of the aforementioned BMUs have been stable and started to increase since the permit cut, although BMUs 41 and 51 have had a very negligible decline over the past few years.

The no-quota BMUs have been increasing rather quickly since 2012. Estimates of growth are 6.0\% (BMU 11) and 2.0\% (BMU 52) annually from 2012-2024. We do not have an explanation for why these areas with unlimited hunting are growing so quickly but hypothesize that it is the high-quality habitat and relatively low/uneven hunting pressure across BMU 11 and 52. There are big tracts of public land in the noquota areas (especially in BMU 11), but generally these WMAs are large wetland complexes and hard to access by hunters. The remainder of the areas are dominated by private land with limited access to hunters. The modeled population trend seems to match the perception among the public and area wildlife staff that bear populations are increasing quickly. Specifically, in BMU 11, bears were non-existent in the early 1990s, but bear range and population size have expanded since then.
Commensurately in BMU 52, there are regular bear sightings in the northern suburbs of the Twin Cities in Anoka, Chisago, and Washington counties.

 $2641 ; 2017=2803 ; 2018=3254 ; 2019=3450 ; 2020=3691 ; 2021=4189 ; 2022=4470 ; 2023=4928$ (record high in the last two decades).
${ }^{\mathrm{b}}$ Beginning in 2011, a procedure was implemented that ensures that all available licenses are purchased (see Table 2).
c Quota zone established in 1982. No-quota zone established in 1987. Surplus licenses from undersubscribed quota areas sold beginning in 2000; originally open only to unsuccessful permit applicants, but beginning in 2003, open to all. In 2011, surplus licenses offered for all lottery licenses not purchased by August 1. Free licenses for 10-and 11-year-olds were available beginning in 2009.
${ }^{\text {d }}$ Quota licenses bought (including surplus)/permits available, or licenses bought (prior to surplus)/permits issued. Beginning in 2008, some permits were issued for area 99 ; these are no-hunt permits, just to increase preference, and are not included in this calculation. In 2011-2022, all unpurchased licenses were put up for sale and were bought. The percent of resident hunters in the quota area each year includes all license types (regular quota, youth, and surplus licenses). This statistic was added to the report in 2021 and was able to easily back-calculate to 2015.
e Number of licensed hunters x percent of license-holders hunting. Percent hunting is based on data from bear hunter surveys conducted during 1981-91, 1998 (86.8\%), 2001 (93.9\%), $2009(95.3 \%), 2018(92.7 \%)$ and $2022(97.8 \%)$. Beginning in 2011 all unpurchased quota licenses were sold as "surplus" in August, and this process is quick and competitive; thus, for 2011-23 all Surplus and Military license-holders were considered to have hunted.
f Sex ratio as reported by hunters; hunters classify about $10 \%$ of female bears as males, so the actual harvest has a lower \%M than shown here. In good food years, the harvest is more male-biased.
${ }^{9}$ Success rates in 2001-2012 were calculated as number of successful hunters/total hunters, rather than bears killed/total hunters, because no-quota hunters could take 2 bears. After 2012, hunters could take 2 bears only if they bought 2 licenses ( 1 quota +1 no-quota). In 2023, 1 hunter shot 2 bears.
${ }^{\mathrm{h}}$ Record high number of no-quota zone licenses purchased in 2021; record high \% of licenses in no-quota zone in 2021 (>50\%; see Fig. 4).
${ }^{1}$ Record high \% males in statewide harvest.
j 2020: record highest success rate in quota zone; 2021: second highest success rate; 2016: third-highest success rate.
${ }^{k}$ In 2020, BMU 451 was broken out of BMU 45 and was an area in the quota zone with an unlimited number of licenses. The quota success rate is calculated without BMU 451 in it to make hunting success estimates comparable across years. The 2023 success rate for BMU 451 is listed in Table 6 and the success rate for the quota area with Area 451 included is $30 \%$.

Fig. 1. Relationship between licenses sold and hunting success (note inverted scale) in quota zone, 1987-2023 (quota and no-quota zones first partitioned in 1987). Number of licenses bought explains 60\% of variation in hunting success during this period. Large variation in hunting success is also attributable to food conditions (e.g., during 2013-2023, when licenses were held relatively constant). Statistics from BMU 451 are not included in this graph to allow for quota zone comparisons with the past.

Fig. 2. Bear management units (BMUs) within quota (white) and no-quota (gray) zones. Hunters in the quota zone are restricted to a single BMU. In 2016, BMU 26 was divided into 27 and 28, and BMU 44 was split into 46 and 47 (BMUs 28 and 47 comprise the Leech Lake Reservation). BMU 14 was split from BMU 12 in 2022. No-quota hunters can hunt anywhere within the gray-colored zone, including the southeast corner of Minnesota (not shown; designated area 60). In 2020, zone 451 was split from 3 deer permit areas of 45 to relieve crop damage in the area. This area is in the quota-zone, but with an unlimited number of participants.

Table 2. Number of bear hunting quota area permits available, 2019-2023. Highlighted values show a change from the previous year.

a No-quota hunters must indicate where they plan to hunt when purchasing their license, but sometimes change their mind or indicate permit areas that are not in bear range. We used the reallocated hunter numbers to account for this discrepancy (see Table 7, bottom).

Table 5. Percent of quota BMU lottery applicants with preference levels 1 (1st-year applicants), $2,3,4$, and 5 who were drawn for a bear permit during 2018-2023. Blank spaces indicate 100\% of applicants were drawn. All preference level 2 applicants were drawn, except where 0 preference level 1 applicants were drawn. Likewise, all preference level 3 applicants were drawn, except where 0 preference level 2 applicants were drawn ${ }^{\text {a }}$.

${ }^{\text {a }}$ As an example, in 2020: BMU 12: 0\% of preference level 1, 2 , and 3 applicants were drawn, $72 \%$ of preference level 4 , and $100 \%$ of preference level 5 and above were drawn for a permit; BMU 22 : $65 \%$ preference level 1 applicants were selected, $100 \%$ all higher preference levels; BMU 45 : no preference level $1-4$ applicants were drawn, $23 \%$ of hunters with preference level 5 were drawn, and $100 \%$ of hunters with preference level 6 and above were drawn.
b BMU 26 was split into $27 / 28$ and BMU 44 was split into $46 / 47$ in 2016.

${ }^{\text {a }}$ Some tooth envelopes were received from hunters who did not register their bear. These were added to the harvest tally: 2013:6; 2014:3; 2015:6; 2016:7; 2017:4; 2018:2; 2019:18; 2020:8; 2021:4; 2022:10; 2023:16. Some hunters with no-quota licenses hunted in the quota zone, and their kills were assigned to the BMU where they apparently hunted: 2013:11; 2014:4; 2015:12; 2016:9; 2017:2; 2018:4*; 2019:4; 2020:6; 2021:11; 2022:10, $2023: 2$ *None were authorized NQ license-holders hunting in quota zone. Some quota area hunters also apparently hunted in the wrong BMU, based on the block where they said they killed a bear, but these were recorded in the BMU where they were assigned (presuming most were misreported kill locations).
${ }^{\mathrm{b}}$ Sex recorded on tooth envelopes may differ from the registered sex. Sex shown on table is the registered sex.
${ }^{\text {c }}$ BMU 60 designates SE Minnesota, which is within No-quota zone. Only two bears have been harvested in this zone in our records dating back to 1980.
${ }^{9}$ BMU 888 designates NQ hunters authorized to remove a conflict bear (typically prior to the hunting season).
Notable harvests:
${ }^{\mathrm{d}}$ Tie for record low harvest.
${ }^{e}$ Highest harvest since 2007.
${ }^{\text {f }}$ Record high harvest for these no-quota zones.

Fig. 4. Trends in statewide bear harvest and proportions of harvest and licenses in the no-quota zones, 1987-2023.

Table 7. Bear hunting success (\%) by BMU, measured as the registered harvest divided by the number of licenses solda, 2018-2023a.

a Registered harvest/licenses instead of harvest/hunters because BMU-year-specific estimates for the proportion of license-holders that hunted are unreliable. Statewide estimates of harvest/hunters are presented in Table 1.
${ }^{\mathrm{b}}$ Record high (or tied record high) success.
${ }^{\text {c Second highest (or tied second highest) success. }}$
${ }^{d}$ Highest success ever for any BMU.
e In 2020, BMU 451 was broken out of BMU 45 and was an area in the quota zone with an unlimited number of licenses. The quota success rate is calculated without BMU 451 in it to make hunting success estimates comparable across years. The success rate for BMU 451 is listed on its own line in the table.
${ }^{\text {i }}$ Since 2013, an attempt was made to differentiate the number of no-quota (NQ) hunters by BMU in order to estimate success rates. When no-quota hunters bought licenses, they recorded the deer block where they anticipated hunting. A significant number chose blocks in the quota zone; those who did not harvest a bear in the quota zone were divided up into NQ-BMUs in proportion to those who chose blocks in or adjacent to NQ-BMUs. A few chose BMU 60 (SE Minnesota); the first bear was harvested there in 2017, 1 more was killed there in 2020. Of these BMU 60 hunters, most seem to have indicated this in error and registered a bear elsewhere in the no-quota. Table shows \% indicating where they planned to hunt (number of hunters in parentheses for BMU 60 and Quota zone):

| BMU | $\mathbf{2 0 2 3}$ | $\mathbf{2 0 2 2}$ | $\mathbf{2 0 2 1}$ | $\mathbf{2 0 2 0}$ | $\mathbf{2 0 1 9}$ |  |

[^2]c The discrepancy between the number recorded on the human-bear conflict survey and the number registered before the opening of the season indicates incomplete data. Similarity between the two values does not necessarily mean the same bears were reported.
d Data only from human-bear conflict survey because registration data do not indicate whether bear was involved in a human-bear conflict. In 2021 and 2022 , data included all validation letter information in this total.
e In 2017, hunters could choose Area 88 (hereafter, 888 in the table) in the quota lottery, and if drawn, could hunt for a conflict bear, if authorized. Starting in 2021, Area 888 was only a designation for hunters willing to take a conflict bear in the quota area on a no-quota license, if so authorized; 17 of these hunters were authorized to do so. Other hunters were authorized to take a conflict bear on a validated license (12 in total).
${ }^{f}$ A permit for non-landowners to take a conflict bear before the bear season was officially implemented in 1992, but some COs individually implemented this program in 1991. Data are based on records from the human-bear conflict survey, not directly from permit receipts. Only 12 bears have been killed by permittees since 2011. In 2020, 13 permits were issued but only 5 bears killed. g According to DNR human-bear conflict policy, trapped conflict bears should not be translocated. Generally, these are cubs that were sent to the rehabilitation facility in Garrison
${ }^{n}$ Car kill data were reported on the monthly human-bear conflict form beginning in 2005. In all previous years, car kill data were from Enforcement's confiscation records. In 2015, confiscation records had more car-kills than the human-bear conflict survey ( 47 vs 33 ), so the higher number is shown here. In 2017, only 1 car-kill was in the confiscation records, and in 2018 there were just 2. In 2017, the electronic system used by managers did not allow for recording of car kills. In 2018, an effort was made to increase car-kill reporting by managers, which was further increased in 2019 by adding a distinct coding for non-confiscated car kills that were either observed or reported by the public.
j Beginning in 2017, Wildlife Managers recorded human-bear conflicts on an all-species wildlife damage app, whereas Conservation Officers continued to submit monthly human-bear conflict survey forms (April-Oct). Beginning in 2019, COs also used an electronic app to record bear complaints (but a different app than wildlife). Because the 2 survey tools are not exactly the same, data are presented separately for each in parenthesis (Wildlife Managers, COs). For consistency, only April-October data are included (in 2017, managers recorded 10 calls in other months; in 2018, 14 calls were in other months; in 2019, 16 calls were in other months; in 2020, 21 calls were in other months; in 2021, 17 calls were in other months; in 2022,14 calls were in other months; in 2023, 2 calls were in other months). For the wildlife manager data, anytime a WCIL row was entered, it is considered an independent complaint, so there are some duplicates when there were repeat issues at the same location.
k Lowest number of conflict bears were killed in 2011 and 2018, since recording began in 1982
${ }^{m}$ Although it is unknown when this started, the information center at Central Office has been fielding human-bear conflict calls. We started to record these data in 2020. To date, some calls $(\sim 40 \%)$ are forwarded on to wildlife managers or conservation officers, but the rest are handled by the information center.

Fig. 5. Trends in human-bear conflict complaints, and conflict bears killed and moved, 1981-2023, showing dramatic effect of change in human-bear conflict policy, and a stable trend over the past decade.

Table 10. Regional bear food indices ${ }^{a}$ in Minnesota's bear range, 1984-2023. Shaded blocks indicate particularly low (<50; pink) or high ( $\geq 70$; green) values.

| 2023 | 70.6 | 81.7 | 84.4 | 69.4 | 73.0 | 78.6 |

a Each bear food index value represents the sum of the mean index values for 14 species, based on surveys conducted in that area. Range-wide mean is derived directly from all surveys conducted in the state (i.e., not by averaging survey area means).
${ }^{\mathrm{b}}$ Record high food rating.

Table 11. Regional mean index values ${ }^{a}$ for bear food species in 2023 compared to the previous 38-year mean (1984-2022) in Minnesota's bear range. Shading indicates particularly high (green) or low (pink) fruit abundance relative to average ( $\geq 1$ point difference for individual foods; $\geq 5$ points difference for totals).

${ }^{\mathrm{b}} n=$ Number of surveys used to calculate area-specific means
c Sample size for the entire range does not equal the sum of the sample sizes of 5 survey areas because some surveys were conducted on the border of 2 or more areas and were included in calculations for both.
d Because of rounding error, these totals may be slightly different than the sum of adding down the columns.

Table 12. Regional productivity index ${ }^{\text {a }}$ for important fall bear foods (oak + hazel + dogwood), 1984-2023. Particularly low ( $\leq 5.0$; yellow) or high ( $\geq 8.0$; tan) values are shaded.

[^3]Fig. 6. Production of fall bear foods (dogwood, oak, hazel) across Minnesota, 2023.

Fig. 7. Number of bears harvested vs. number predicted to be harvested based on number of hunters and fall food production statewide 1984-2023. Regression for the dataset included an interaction term between food and hunters to better predict changes in harvest when foods were extremely high or low.

Fig 8. Percent of hunters submitting useable bear teeth for aging (vital for population monitoring, see Figs. 10-12). Cooperation levels exceeded $80 \%$ when registration stations were paid to extract teeth (this practice ended in 1993), and in recent years after a series of reminder letters (however, no letter was sent after 2017).

Fig. 9. Percent of hunters who submitted a bear tooth in 2023 by method of registration (top panel) and by BMU (bottom panel). Beginning in 2013, hunters could register their bear by phone, internet, and in person at a station. The 2023 statewide submission average ( $84 \%$; red line, bottom panel) was above the long-term average ( $77 \%$ ).

BMU

Fig. 10. Population trends during 1996-2024 derived from Allen et al. (2018) model statewide estimates ( $\pm 95 \%$ credible intervals), and population estimates for quota and no-quota zones.

Fig. 11. Trends in proportion of male bears in statewide harvest at each age, 1-10 years, grouped in 5 -year time blocks, 19802023. Higher harvest rates result in steeper curves because males in the living population are reduced faster than females. Fitting a line to the data for each time block and predicting the age at which $50 \%$ of the harvest is male (dashed orange horizontal line) yields approximately the inverse of the harvest rate (derived rates are shown in inset). Flatter curves in recent years indicate lower harvest rates (e.g., 2015-19 lower than 1980-84), but a slight increase in recent years.

Fig 12. Allen et al. (2018) BMU-level, pre-hunt estimates 2000-2024. The vertical black line in 20122013 represents when quota permits were cut by $>50 \%$ and have remained stable at low levels since then. The dashed lines represent the $95 \%$ pointwise credible intervals of the population estimate. With the small population size at BMU level, estimates of population trend are more reliable than actual population size. BMU harvest in area 22 is too small to reliably model. BMU population estimates are compiled into pre-2017 BMUs (e.g., BMU 27 and 28 are aggregated into BMU 26; BMU 46 and 47 are aggregated into BMU 44).

Population trend over 1996-2024: BMUs 11 and 52

[^0]:    a Beginning in 2011, all licenses not purchased by permittees were sold as "surplus". In all cases (see footnote b), all the surplus licenses were purchased. Surplus = Permits available (Table 2) minus Bought licenses.
    ${ }^{\mathrm{b}}$ Beginning in 2008, applicants could apply for area 99 in order to increase future preference, but not buy a license; these are not included in the total number of applications (unlike Table 1 , where they are included). This number also includes the permits sold in area 451.
    c Beginning in 2020, applicants could buy a license over the counter for area 451. This was an area in the quota zone with no limit on the quota and all licenses are considered surplus licenses.
    This is not an area for lottery or applications; only surplus licenses could be purchased.

[^1]:    a The low proportion of total harvest taken during the opening week ( $<60 \%$ ) reflects a high abundance of natural foods.
    b The slow start the first week was likely due to especially warm weather.

[^2]:    a Maximum number of people turning in a human-bear conflict report each month. Monthly reports were required beginning in 1984 and included cases of zero complaints. In 2017, the recording system was changed, where Wildlife Managers only recorded actual complaints (not zero complaints), generally at the time the complaint was received. Since then, the number reflects the total number of people receiving and recording at least 1 complaint during that year. For consistency, the records from Conservation Officers were handled the same way. Beginning July 2019 , COs recorded complaints electronically and individually (as they occurred), similar to Wildlife Managers (but using a different recording system).
    ${ }^{\mathrm{b}}$ If a complaint was handled by phone, it means a site visit was not made.

[^3]:    a Values represent the sum of mean production scores for hazel, oak, and dogwood, derived from surveys conducted in each survey area. Range-wide mean is for all surveys conducted in the state (i.e. not an average of survey area means). ${ }^{\mathrm{b}}$ Record low fall food score in survey area.
